There are close similarities between the Weihrauch lattice and the zoo of axiom systems in reverse mathematics. Following these similarities has often allowed researchers to translate results from one setting to the other. However, amongst the *big five* axiom systems from reverse mathematics, so far  $\text{ATR}_0$  has no identified counterpart in the Weihrauch degrees. We explore and evaluate several candidates, and conclude that the situation is complicated.

## 1 Introduction

Reverse mathematics [41] is a program to find the sufficient and necessary axioms to prove theorems of mathematics (that can be formalized in second-order arithmetic). For this, a base system ( $\text{RCA}_0$ ) is fixed, and then equivalences between theorems and certain benchmark axioms are proven. Sometimes, a careful reading of the original proof of the theorem reveals which of the benchmark axioms are used, and the main challenge is to show that the theorem indeed implies those axioms (hence the name *reverse* mathematics). A vast number of theorems turned out to be equivalent to one of only five systems:  $\text{RCA}_0$ ,  $\text{WKL}_0$ ,  $\text{ACA}_0$ ,  $\text{ATR}_0$  and  $\mathbf{\Pi}^1_1\text{-CA}_0$ . While recently attention has shifted to theorems **not** equivalent to one of the *big five*, the big five still occupy a central role in the endeavour.

Computational metamathematics in the Weihrauch lattice starts with the observation that many theorems in analysis and other areas of mathematics have  $\Pi_2$ -*gestalt*, i.e. are of the form  $\forall x \in \mathbf{X}(Q(x) \rightarrow \exists y \in \mathbf{Y} P(x, y))$ , and can hence be seen as computational tasks: Given some  $x \in \mathbf{X}$  satisfying  $Q(x)$ , find a suitable witness  $y \in \mathbf{Y}$ . This task can also be viewed as a multivalued partial function  $f : \subseteq \mathbf{X} \rightrightarrows \mathbf{Y}$ , and thus the precise definition of Weihrauch reducibility (given in §2.2 below) deals with this kind of objects. Often, the task cannot be solved algorithmically (equivalently, the multivalued function is not computable). The research programme (as formulated by Gherardi and Marcone [20], Pauly [34, 36] and in particular Brattka and Gherardi [7, 6]) is to compare the degree of impossibility as follows: Assume we had a black box to solve the task for Theorem B. Can we solve the task for Theorem A using the black box exactly once? If so, then  $A \leq_w B$ ,  $A$  is Weihrauch reducible to  $B$ .

As provability in RCA<sub>0</sub> is closely linked to computability, it is maybe not that surprising that very often, classification in reverse math can be translated easily into Weihrauch reductions<sup>1</sup>. While there are a number of obstacles for precise correspondence (see [23] for a detailed discussion), the resource-sensitivity of Weihrauch reductions might be the most obvious one: A proof in reverse mathematics can use a principle multiple times, a Weihrauch reduction uses its black box once. This obstacle does not apply to RCA<sub>0</sub> or WKL<sub>0</sub> classifications.

The analogue of RCA<sub>0</sub> are the computable principles, the analogue of WKL<sub>0</sub> is C<sub>2 $\mathbb{N}$</sub>  (closed choice on Cantor space), and the analogue of ACA<sub>0</sub> is lim or finite iterations thereof. Theorems equivalent to  $\Pi_1^1$ -CA<sub>0</sub> have not yet been studied in the Weihrauch lattice, but an obvious analogue of  $\Pi_1^1$ -CA<sub>0</sub> is readily defined as the function which maps a countable sequence of trees to the characteristic function of the set of indices corresponding to well-founded trees. This leaves ATR<sub>0</sub> out of the big five, leading Marcone to initiate the search for an analogue in the Weihrauch lattice at a Dagstuhl meeting on Weihrauch reducibility [13].

Two candidates have been put forth as potential answers, UC<sub>N $\mathbb{N}$</sub>  and C<sub>N $\mathbb{N}$</sub>  (unique choice and closed choice on Baire space). We will examine some evidence for both of them, and show that the question is not as easily answered as those for other big five. Our main focus is on three particular theorems equivalent to ATR<sub>0</sub> in reverse mathematics: Comparability of well orderings, open determinacy on Baire space<sup>2</sup> and the perfect tree theorem.

**Theorem** (Comparability of well orderings). If  $X$  and  $Y$  are well orderings over  $\mathbb{N}$ , then  $|X| \leq |Y|$  or  $|Y| \leq |X|$ .

**Theorem** (Open determinacy). Consider a two-player infinite sequential game with moves from  $\mathbb{N}$ . Let the first player have an open winning set. Then one player has a winning strategy.

**Theorem** (Perfect Tree Theorem). If  $T \subseteq \mathbb{N}^{<\omega}$  is a tree, then either  $[T]$  is countable or  $T$  has a perfect subtree.

**Structure of the paper** In Section 2 we recall the prerequisite notions about Weihrauch reducibility. While reverse mathematics serves as the motivation for this paper, its results are not invoked in our proofs, hence we do not expand on this area. In Section 3 we recall two Weihrauch degrees of central importance, unique choice UC<sub>N $\mathbb{N}$</sub>  and closed choice C<sub>N $\mathbb{N}$</sub>  on Baire space. We then prove some equivalences to those for variants of comprehension and separation principles. In Section 4, we re-examine the strength of a separation principle, which is shown to be equivalent to  $\Sigma_1^1$ -WKL, weak König's lemma for  $\Sigma_1^1$ -trees (Theorem 4.3). The comparability of well orderings is studied in Section 5. We see two variants, one of which we prove to be equivalent to UC<sub>N $\mathbb{N}$</sub>  (Theorem 5.5) whereas the other resists full classification (Question 5.8).

Open determinacy and the perfect tree theorem are investigated in Sections 6 and 7. Both principles are formulated as disjunctions, and the versions where we know in which case we are are proven to be equivalent to UC<sub>N $\mathbb{N}$</sub>  or C<sub>N $\mathbb{N}$</sub>  in Section 6. The results about open determinacy can be seen as uniform versions of the study of the complexity of winning strategies in [2]. If no case is fixed, we arrive at Weihrauch degrees not previously studied. Some of their properties are exhibited in Section 7. Since the degrees studied in Section 7 are not very well behaved, we introduce the canonical principle TC<sub>N $\mathbb{N}$</sub> , the total continuation of closed choice in Section 8. We prove that up to finite parallelization, it is equivalent to the two-sided versions of open

---

<sup>1</sup>The reverse direction would also be possible, but as reverse mathematics is the older field, occurs seldom in practice.

<sup>2</sup>The version for Cantor space has been studied in the Weihrauch degrees by Le Roux and Pauly [29].

determinacy and the perfect tree theorem, and show some additional properties of the degree. Some concluding remarks and open questions are found in Section 9.

The following illustrates the strength of key benchmark principles in this article:

$$\text{UC}_{\mathbb{N}^{\mathbb{N}}} <_{\text{W}} \Sigma_1^1\text{-WKL} <_{\text{W}} \mathcal{C}_{\mathbb{N}^{\mathbb{N}}} <_{\text{W}} \text{TC}_{\mathbb{N}^{\mathbb{N}}} <_{\text{W}} \widehat{\text{TC}_{\mathbb{N}^{\mathbb{N}}}} <_{\text{W}} \Pi_1^1\text{-CA}.$$

## 2 Background on represented spaces and Weihrauch degrees

For background on the theory of represented spaces we refer to [38], for an introduction to and survey of Weihrauch reducibility we point the reader to [12].

### 2.1 Represented spaces

**Definition 2.1.** A represented space  $\mathbf{X}$  is a set  $X$  together with a partial surjection  $\delta_{\mathbf{X}} : \subseteq \mathbb{N}^{\mathbb{N}} \rightarrow X$ .

A partial function  $F : \subseteq \mathbb{N}^{\mathbb{N}} \rightarrow \mathbb{N}^{\mathbb{N}}$  is called a *realizer* of a function  $f : \subseteq \mathbf{X} \rightarrow \mathbf{Y}$  between represented spaces, if  $f(\delta_{\mathbf{X}}(p)) = \delta_{\mathbf{Y}}(F(p))$  holds for all  $p \in \text{dom}(f \circ \delta_{\mathbf{X}})$ . We denote  $F$  being an realizer of  $f$  by  $F \vdash f$ . We then call  $f : \subseteq \mathbf{X} \rightarrow \mathbf{Y}$  *computable* (respectively *continuous*), iff it has a computable (respectively continuous) realizer.

Represented spaces can adequately model most spaces of interest in *everyday mathematics*. For our purposes, we only need a few specific spaces that we discuss in the following, as well as some constructions of hyperspaces.

The category of represented spaces and continuous functions is cartesian-closed, by virtue of the UTM-theorem. Thus, for any two represented spaces  $\mathbf{X}, \mathbf{Y}$  we have a represented spaces  $\mathcal{C}(\mathbf{X}, \mathbf{Y})$  of continuous functions from  $\mathbf{X}$  to  $\mathbf{Y}$ . The expected operations involving  $\mathcal{C}(\mathbf{X}, \mathbf{Y})$  (evaluation, composition, (un)currying) are all computable. Using the Sierpiński space  $\mathbb{S}$  with underlying set  $\{\top, \perp\}$  and representation  $\delta_{\mathbb{S}} : \mathbb{N}^{\mathbb{N}} \rightarrow \{\top, \perp\}$  defined via  $\delta_{\mathbb{S}}(\perp)^{-1} = \{0^\omega\}$ , we can then define the represented space  $\mathcal{O}(\mathbf{X})$  of *open* subsets of  $\mathbf{X}$  by identifying a subset of  $\mathbf{X}$  with its (continuous) characteristic function into  $\mathbb{S}$ . Since countable *or* and binary *and* on  $\mathbb{S}$  are computable, so are countable union and binary intersection of open sets. The space  $\mathcal{A}(\mathbf{X})$  of closed subsets is obtained by taking formal complements, i.e. the names for  $A \in \mathcal{A}(\mathbf{X})$  are the same as the names of  $X \setminus A \in \mathcal{O}(\mathbf{X})$  (i.e. we are using the negative information representation).

We indicate with  $\mathbf{Tr}$  the represented space of trees on  $\mathbb{N}$  represented in an obvious way. The computable map  $[\ ] : \mathbf{Tr} \rightarrow \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  maps a tree to its set of infinite paths, and has a computable multivalued inverse. In other words, one can compute a code of a tree  $T$  from a code of a closed set  $[T]$ , and vice versa.

Given a represented space  $\mathbf{X}$  and  $k \in \mathbb{N}$ , using Borel codes, the collections  $\Sigma_k^0(\mathbf{X})$  (respectively  $\Pi_k^0(\mathbf{X})$ ) of  $\Sigma_k^0$  (respectively  $\Pi_k^0$ ) subsets of  $\mathbf{X}$  can be naturally viewed as a represented space, cf. [3, 21, 37]. Equivalently, we can use the jumps of  $\mathbb{S}$  to characterize these spaces. We find that  $\mathcal{A}$  and  $\Pi_1^0$  (respectively  $\mathcal{O}$  and  $\Sigma_1^0$ ) are identical.

The collection  $\Sigma_1^1(\mathbf{X})$  of analytic subsets of  $\mathbf{X}$  can also be represented in a straightforward manner:  $p$  is a name of a  $\Sigma_1^1$  set  $S \subseteq \mathbf{X}$  iff  $p$  is a name of a closed set  $P \subseteq \mathbb{N}^{\mathbb{N}} \times \mathbf{X}$  such that  $S = \{x \in \mathbf{X} : (\exists g)(g, x) \in P\}$ . Equivalently ([39, Proposition 35]), we can define the space  $\mathbb{S}_{\Sigma_1^1}$  by letting it have the underlying set  $\{\top, \perp\}$ , and letting  $p \in \mathbb{N}^{\mathbb{N}}$  be a name for  $\top$  iff the tree on  $\mathbb{N}$  coded by  $p$  is ill-founded; and then identify  $\Sigma_1^1(\mathbf{X})$  with  $\mathcal{C}(\mathbf{X}, \mathbb{S}_{\Sigma_1^1})$ . Again, the collection  $\Pi_1^1(\mathbf{X})$

of coanalytic subsets of  $\mathbf{X}$  is represented in an obvious way by taking formal complements. We define the space  $\mathbb{S}_{\Sigma_1^1}$  with underlying set  $\{\top, \perp\}$ , so that  $p \in \mathbb{N}^\mathbb{N}$  is a name for  $\top$  iff the tree on  $\mathbb{N}$  coded by  $p$  is well-founded.

We first check that basic operations on these represented spaces are well-behaved.

**Lemma 2.2.** The following operations are computable:

1.  $\vee, \wedge : \mathbb{S}_{\Sigma_1^1} \rightarrow \mathbb{S}_{\Sigma_1^1}$
2.  $\exists : \Sigma_1^1(\mathbf{X}) \rightarrow \mathbb{S}_{\Sigma_1^1}$ , mapping non-empty sets to  $\top$  and the empty set to  $\perp$ .
3.  $\text{id}, \neg : \mathbb{S} \rightarrow \mathbb{S}_{\Sigma_1^1}$

*Proof.* 1. For  $\vee$ , we need to show that given a sequence of trees we can compute a tree that is ill-founded iff one of the contributing trees is. This can be done by simply joining them at the root. For  $\wedge$ , we need a tree that is ill-founded iff all them are. For that, we can take the product of the trees (e.g. as in [33]).

2. From  $f \in \mathcal{C}(\mathbb{N}^\mathbb{N}, \mathbb{S}_{\Sigma_1^1})$  we can compute by type-conversion some  $g : \mathbb{N}^\mathbb{N} \times \mathbb{N}^\mathbb{N} \rightarrow \mathbb{S}$  such that  $f(p) = \top$  iff  $\exists q \in \mathbb{N}^\mathbb{N} g(p, q) = \perp$ . But then  $\exists p \in \mathbb{N}^\mathbb{N} f(p) = \top \Leftrightarrow \exists \langle p, q \rangle \in \mathbb{N}^\mathbb{N} g(p, q) = \perp$ , and we are done.
3. For  $\neg : \mathbb{S} \rightarrow \mathbb{S}_{\Sigma_1^1}$ , let the tree  $T$  given  $p \in \mathbb{N}^\mathbb{N}$  be defined by  $w \in T$  iff  $\forall n \leq |w| p(n) = 0$ . For  $\text{id} : \mathbb{S} \rightarrow \mathbb{S}_{\Sigma_1^1}$ , we let  $T$  have only branches of the form  $n0^\omega$ , and such a branch is present iff  $p(n) \neq 0$ .

□

**Proposition 2.3.** The following operations are computable for any represented space  $\mathbf{X}$ ,  $k > 0$ :

1.  $\Sigma_1^1(\mathbf{X})^\mathbb{N} \rightarrow \Sigma_1^1(\mathbf{X}), (A_n)_n \mapsto \bigcup_{n \in \mathbb{N}} A_n$  (countable union);
2.  $\Sigma_1^1(\mathbf{X})^\mathbb{N} \rightarrow \Sigma_1^1(\mathbf{X}), (A_n)_n \mapsto \bigcap_{n \in \mathbb{N}} A_n$  (countable intersection);
3.  $\Sigma_1^1(\mathbf{X} \times \mathbf{Y}) \rightarrow \Sigma_1^1(\mathbf{Y}), A \mapsto \{y \in \mathbf{Y} \mid \exists x \in \mathbf{X} (x, y) \in A\}$
4.  $\Sigma_k^0(\mathbf{X}) \rightarrow \Sigma_1^1(\mathbf{X}), \Pi_k^0(\mathbf{X}) \rightarrow \Sigma_1^1(\mathbf{X}), \Sigma_k^0(\mathbf{X}) \rightarrow \Pi_1^1(\mathbf{X}), \Pi_k^0(\mathbf{X}) \rightarrow \Pi_1^1(\mathbf{X})$  (inclusions);
5.  $\Sigma_k^0(\mathbb{N}^\mathbb{N} \times \mathbf{X}) \rightarrow \Sigma_1^1(\mathbf{X}), \Pi_k^0(\mathbb{N}^\mathbb{N} \times \mathbf{X}) \rightarrow \Sigma_1^1(\mathbf{X})$ , such that

$$B \mapsto A = \left\{ x \in X : \exists g \in \mathbb{N}^\mathbb{N} (g, x) \in B \right\};$$

6.  $\Sigma_k^0(\mathbb{N}^\mathbb{N} \times \mathbf{X}) \rightarrow \Pi_1^1(\mathbf{X}), \Pi_k^0(\mathbb{N}^\mathbb{N} \times \mathbf{X}) \rightarrow \Pi_1^1(\mathbf{X})$ , such that

$$B \mapsto A = \left\{ x \in X : \forall g \in \mathbb{N}^\mathbb{N} (g, x) \in B \right\};$$

7.  $\Pi_1^0(\mathbb{N}^\mathbb{N} \times \mathbf{X}) \rightarrow \Pi_1^1(\mathbf{X})$ , such that

$$C \mapsto A = \left\{ x \in X : \exists ! g \in \mathbb{N}^\mathbb{N} (g, x) \in C \right\}.$$

*Proof.* (1-6) These all follow directly from Lemma 2.2 together with function composition.

(7) It is well-known that  $a \in \mathbb{N}^{\mathbb{N}}$  is hyperarithmetical relative to  $\{a\} \in \mathbf{\Pi}_1^0(\mathbb{N}^{\mathbb{N}})$  (cf. Corollary 3.3 and accompanying remarks below). The section map  $(x, C) \mapsto \{y \in \mathbb{N}^{\mathbb{N}} \mid (y, x) \in C\} : \mathbf{X} \times \mathbf{\Pi}_1^0(\mathbb{N}^{\mathbb{N}} \times \mathbf{X}) \rightarrow \mathbf{\Pi}_1^0(\mathbb{N}^{\mathbb{N}})$  is computable, see [38, Proposition 4.2 (9)]. Thus, we find that

$$A = \{x \in \mathbf{X} \mid \exists y \in \text{HYP}(x) \ (y, x) \in C\} \cap \{x \in \mathbf{X} \mid \forall y, z ((y, x), (z, x) \in C \rightarrow y = z)\}.$$

The first term effectively defines a  $\mathbf{\Pi}_1^1$ -set due to Kleene's HYP-quantification theorem [26, 27], and the second term is directly defined a  $\mathbf{\Pi}_1^1$ -set. The claim thus follows using that intersection is a computable operation on  $\mathbf{\Pi}_1^1$ -sets from (2).  $\square$

We denote by **LO** and **WO** the represented spaces respectively of linear orderings and countable well orderings with domain contained in  $\mathbb{N}$  (thus **WO** is a subspace of **LO**). We may assume without any loss of generality that, for all  $X \in \mathbf{LO}$ ,  $0 \notin X$ . If  $X \in \mathbf{LO}$  we use interchangeably  $\mathbf{WO}(X)$  and  $X \in \mathbf{WO}$ . If  $X \in \mathbf{WO}$  we indicate its order type by  $|X|$ . Given some tree  $T \subseteq \mathbb{N}^{<\omega}$ , we define the Kleene-Brouwer ordering  $\preceq_{KB}$  on  $T$  as the transitive closure of  $w \preceq_{KB} u$  if  $w \sqsupseteq u$  and  $un \preceq_{KB} um$  if  $n \leq m$ .

**Observation 2.4.** The map  $\text{KB} : \mathbf{Tr} \rightarrow \mathbf{LO}$  mapping a tree to its Kleene-Brouwer ordering is computable. We have  $\mathbf{WO}(\text{KB}(T))$  iff  $T$  is well-founded.

We need a technical definition, which can be found in [41, Definition V.6.4], for some of our proofs related to well orderings.

**Definition 2.5** (double descent tree). If  $X, Y \in \mathbf{LO}$  the *double descent tree*  $\mathbf{T}(X, Y)$  is the set of all finite sequences of the form  $\langle (m_0, n_0), (m_1, n_1), \dots, (m_{k-1}, n_{k-1}) \rangle \in \mathbb{N}^{<\mathbb{N}}$  such that

- $m_0, m_1, \dots, m_{k-1} \in X$  and  $m_0 >_X m_1 >_X \dots >_X m_{k-1}$ ,
- $n_0, n_1, \dots, n_{k-1} \in Y$  and  $n_0 >_Y n_1 >_Y \dots >_Y n_{k-1}$ .

We define the linear ordering  $X * Y = \text{KB}(\mathbf{T}(X, Y))$ .

**Observation 2.6.**  $(X, Y) \mapsto (X * Y) : \mathbf{LO} \times \mathbf{LO} \rightarrow \mathbf{LO}$  is computable.

With an abuse of notation, we use  $\mathbb{Q}$  and  $\mathbb{N}$  to denote respectively a computable presentation of the standard linear ordering of rational numbers and of the well ordering of natural numbers.

**Lemma 2.7.** Let  $X, Y \in \mathbf{LO}$ .

1. If  $\mathbf{WO}(X)$  then  $X * Y$  and  $Y * X$  are well orderings.
2. If  $\mathbf{WO}(X)$  and  $\neg \mathbf{WO}(Y)$ , then  $|X| \leq |X * Y|$ .
3. If  $\mathbf{WO}(Y)$ , then  $|X * Y| \leq |\mathbb{Q} * Y|$ .

*Proof.* The proofs of 1 and 2 can be found in Lemma V.6.5 of [41]. In order to prove 3, consider a function  $g : X \rightarrow \mathbb{Q}$  such that, for all  $x, x' \in X$ ,

- (a)  $x <_X x' \rightarrow g(x) <_{\mathbb{Q}} g(x')$ ,
- (b)  $x <_{\mathbb{N}} x' \rightarrow g(x) <_{\mathbb{N}} g(x')$ .

It is easy to see that such a function exists. Define then  $\hat{g} : (X * Y) \rightarrow (\mathbb{Q} * Y)$  by putting  $\hat{g}(\langle (x_0, y_0), \dots, (x_{k-1}, y_{k-1}) \rangle) := \langle (g(x_0), y_0), \dots, (g(x_{k-1}), y_{k-1}) \rangle$ . Property a. of  $g$  guarantees that  $\hat{g}$  is well-defined and property b. implies that  $\hat{g}$  respects the Kleene-Brouwer orderings of the double descent trees  $X * Y$  and  $\mathbb{Q} * Y$ .  $\square$

## 2.2 Weihrauch reducibility

Intuitively,  $f$  being Weihrauch reducible to  $g$  means that there is an otherwise computable procedure to solve  $f$  by invoking an oracle for  $g$  exactly once. We thus obtain a very fine-grained picture of the relative strength of partial multivalued functions. Consequently, a Weihrauch equivalence is a very strong result compared to other approaches that allow more generous access to the principle being reduced to. In the following, let  $\langle \cdot \rangle$  denote the standard pairing function on Baire space.

**Definition 2.8** (Weihrauch reducibility). Let  $f, g$  be multivalued functions on represented spaces. Then  $f$  is said to be *Weihrauch reducible* to  $g$ , in symbols  $f \leq_W g$ , if there are computable functions  $K, H : \subseteq \mathbb{N}^\mathbb{N} \rightarrow \mathbb{N}^\mathbb{N}$  such that  $(p \mapsto K\langle p, GH(p) \rangle) \vdash f$  for all  $G \vdash g$ .

If there are computable functions  $K, H : \subseteq \mathbb{N}^\mathbb{N} \rightarrow \mathbb{N}^\mathbb{N}$  such that  $KGH \vdash f$  for all  $G \vdash g$ , then  $f$  is *strongly Weihrauch reducible* to  $g$ , in symbols  $f \leq_{sw} g$ .

The relations  $\leq_W, \leq_{sw}$  are reflexive and transitive. We use  $\equiv_W (\equiv_{sw})$  to denote equivalence and by  $<_W$  we denote strict reducibility. Both Weihrauch degrees [35] and strong Weihrauch degrees [17] form lattices, the former being distributive and the latter not (in general, Weihrauch degrees behave more naturally than strong Weihrauch degrees).

Rather than the lattice operations, we will use two kinds of products in this work: The parallel product  $f \times g$  is just the usual cartesian product of (multivalued) functions, which is readily seen to induce an operation on (strong) Weihrauch degrees. We call  $f$  a *cylinder*, if  $f \equiv_{sw} (\text{id}_{\mathbb{N}^\mathbb{N}} \times f)$ , and note that for cylinders, Weihrauch reducibility and strong Weihrauch reducibility coincide.

The compositional product  $f \star g$  satisfies that

$$f \star g \equiv_W \max_{\leq_W} \{f_1 \circ g_1 \mid f_1 \leq_W f \wedge g_1 \leq_W g\}$$

and thus is the hardest problem that can be realized using first  $g$ , then something computable, and finally  $f$ . The existence of the maximum is shown in [15]. Both products as well as the lattice-join can be interpreted as logical *and*, albeit with very different properties. The sequential product  $\star$  is not commutative, however, it is the only one that admits a matching implication [15, 22].

Two further (unary) operations on Weihrauch degrees are relevant for us, finite parallelization  $f^*$  and parallelization  $\widehat{f}$ . The former has as input a finite tuple of instances to  $f$  and needs to solve all of them, the latter takes and solves a countable sequences of instances. Both operations are closure operators in the Weihrauch lattice. They can be used to relax the requirement of using the oracle only once, if so desired, by looking at the relevant quotient lattices.

In passing, we will refer to the third operation, the jump from [11] (studied further in [4], denoted by  $f'$ ). We use  $f^{(n)}$  to denote the result of applying the jump  $n$ -times. The jump only preserves strong Weihrauch degrees. The input to  $f'$  is a sequence converging (with unknown speed) to an input of  $f$ , the output is whatever  $f$  would output on the limit.

The well-studied Weihrauch degrees most relevant for us are unique closed choice and closed choice (on Baire space), to which we dedicate the following Section 3. Two other degrees we will refer to are  $\text{LPO} : \mathbb{N}^\mathbb{N} \rightarrow \{0, 1\}$  and  $\lim : \subseteq (\mathbb{N}^\mathbb{N})^\omega \rightarrow \mathbb{N}^\mathbb{N}$ . These are defined via  $\text{LPO}(p) = 1$  iff  $p = 0^\omega$ , and  $\lim((p_i)_{i \in \mathbb{N}}) = \lim_{i \rightarrow \infty} p_i$ . They are related by  $\widehat{\text{LPO}} \equiv_W \lim$ . The importance of  $\lim$  is found partially in the observation from [3] that  $\lim$  is complete for Baire class 1 functions, and more generally, that  $\lim^{(n)}$  is complete for Baire class  $n + 1$  functions.

### 3 $\mathbf{UC}_{\mathbb{N}^{\mathbb{N}}}$ and $\mathbf{C}_{\mathbb{N}^{\mathbb{N}}}$

The two Weihrauch degrees of central importance for this paper are unique closed choice and closed choice (on Baire space). These are defined as follows:

**Definition 3.1.** Given a represented space  $\mathbf{X}$ , let  $C_{\mathbf{X}} : \subseteq \mathcal{A}(\mathbf{X}) \rightrightarrows \mathbf{X}$  be defined via  $x \in C_{\mathbf{X}}(A)$  iff  $x \in A$  (thus,  $A \in \text{dom}(C_{\mathbf{X}})$  iff  $A \neq \emptyset$ ). Let  $UC_{\mathbf{X}}$  be the restriction of  $C_{\mathbf{X}}$  to singletons.

In particular,  $UC_{\mathbf{X}}$  is capable of finding an element of a given  $\Pi_1^0$  singleton in  $\mathbf{X}$ . In [37] Pauly introduced the notion of iterating a Weihrauch degree  $f$  over a given countable ordinal, this is denoted by  $f^\dagger$ . It is then shown that:

**Theorem 3.2** ([37]).  $UC_{\mathbb{N}^{\mathbb{N}}} \equiv_W \lim^\dagger$

One can read the above result as a very uniform version of the famous classical result that the Turing downward closures of  $\Pi_1^0$  singletons in  $\mathbb{N}^{\mathbb{N}}$  exhausts the hyperarithmetical hierarchy (cf. [40, Corollary II.4.3]).

**Remark:** Seeing that  $\text{ATR}_0$  asserts the existence of Turing jumps iterated along some countable ordinal and since  $\lim$  is equivalent to the Turing jump, it may seem as if this theorem already establishes that  $UC_{\mathbb{N}^{\mathbb{N}}}$  is the Weihrauch degree corresponding to  $\text{ATR}_0$ . There is a significant difference here though in what is meant by countable ordinal: In  $\lim^\dagger$ , the input includes a code for something which is an ordinal in the surrounding meta-theory. In particular, any computable ordinal can be used *for free*. For  $\text{ATR}_0$  the notion of countable ordinal is that of the model used. For example, an ill-founded computable linear order without hyperarithmetical descending chains (Kleene, see [40, Chapter 3, Lemma 2.1]) counts as an ordinal in the  $\omega$ -model  $\mathbf{HYP}$  consisting exactly of hyperarithmetical sets, and a similar phenomenon may happen in non- $\beta$ -models of  $\text{ATR}_0$ . Things get worse if non- $\omega$ -models are considered:  $\text{ATR}_0$  (indeed, any consistent c.e. theory, of course) fails to prove well-foundedness of some computable ordinals.

Note that  $\lim^\dagger$  roughly corresponds to a (uniform) hyperarithmetical reduction, and therefore Theorem 3.2, for instance, implies the following:

**Corollary 3.3.** Whenever  $\{a\} \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  is computable, then  $a \in \mathbb{N}^{\mathbb{N}}$  is hyperarithmetical.

**Corollary 3.4.** If  $f \leq_W UC_{\mathbb{N}^{\mathbb{N}}}$  for  $f : \subseteq \mathbb{N}^{\mathbb{N}} \rightrightarrows \mathbf{X}$ , then for every  $x \in \text{dom}(f)$ ,  $f(x)$  contains some  $y$  hyperarithmetical relative to  $x$ .

Corollary 3.3 is a well-known classical fact saying that every  $\Pi_1^0$  singleton is hyperarithmetical. Indeed, Spector showed that every  $\Sigma_1^1$  singleton is hyperarithmetical (cf. [40, Theorem I.1.6]). Thus, it is natural to ask whether choice from  $\Sigma_1^1$  singletons has exactly the same strength as  $UC_{\mathbb{N}^{\mathbb{N}}}$ .

One can generalize Definition 3.1 to any  $\Gamma \in \{\Sigma_k^i, \Pi_k^i, \Delta_k^i\}$  in a straightforward manner: Let  $\Gamma\text{-}C_{\mathbf{X}} : \subseteq \Gamma(\mathbf{X}) \rightrightarrows \mathbf{X}$  be defined via  $x \in \Gamma\text{-}C_{\mathbf{X}}(A)$  iff  $x \in A$ . In other words, it sends a code of a  $\Gamma$ -definition of  $A$  to an element of  $A$ . Let  $\Gamma\text{-}UC_{\mathbf{X}}$  be the restriction of  $\Gamma\text{-}C_{\mathbf{X}}$  to singletons. For instance,  $\Sigma_1^1$ -unique choice  $\Sigma_1^1\text{-}UC_{\mathbb{N}^{\mathbb{N}}} : \subseteq \Sigma_1^1(\mathbb{N}^{\mathbb{N}}) \rightarrow \mathbb{N}^{\mathbb{N}}$  is a partial function which, given a  $\Sigma_1^1$ -code of a singleton  $\{x\} \subseteq \mathbb{N}^{\mathbb{N}}$ , returns its unique element  $x$ . We will see below (in Theorem 3.11) that  $\Sigma_1^1\text{-}UC_{\mathbb{N}^{\mathbb{N}}} \equiv_W UC_{\mathbb{N}^{\mathbb{N}}}$ .

We now explore the strength of  $C_{\mathbb{N}^{\mathbb{N}}}$ .

**Theorem 3.5** (Kleene [26]). There exists computable non-empty  $A \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  containing no hyperarithmetical point.

That is, there is a nonempty  $\Pi_1^0$  set  $A \subseteq \mathbb{N}^\mathbb{N}$  with no hyperarithmetical element. This shows that  $C_{\mathbb{N}^\mathbb{N}}$  has a computable instance with no hyperarithmetical solution. Let  $NHA : \mathbb{N}^\mathbb{N} \rightrightarrows \mathbb{N}^\mathbb{N}$  be defined via  $q \in NHA(p)$  iff  $q$  is not hyperarithmetical relative to  $p$ .

**Corollary 3.6.**  $NHA \not\leq_W UC_{\mathbb{N}^\mathbb{N}}$  but  $NHA \leq_W C_{\mathbb{N}^\mathbb{N}}$ .

We now get the separation between  $UC_{\mathbb{N}^\mathbb{N}}$  and  $C_{\mathbb{N}^\mathbb{N}}$ .

**Corollary 3.7.**  $UC_{\mathbb{N}^\mathbb{N}} <_W C_{\mathbb{N}^\mathbb{N}}$ .

There are a number of variants of unique choice, comprehension and separation that are all equivalent to  $UC_{\mathbb{N}^\mathbb{N}}$  w.r.t. Weihrauch reducibility. We explore some of these next:

**Definition 3.8** ( $\Sigma_1^1$ -Separation). Let  $\Sigma_1^1\text{-Sep} : \subseteq (\mathbf{Tr} \times \mathbf{Tr})^\mathbb{N} \rightrightarrows 2^\mathbb{N}$  be the multivalued function with  $\text{dom}(\Sigma_1^1\text{-Sep}) = \{(S_n, T_n)_{n \in \mathbb{N}} : \forall n ([S_n] = \emptyset \vee [T_n] = \emptyset)\}$  that maps any sequence  $(S_n, T_n)_{n \in \mathbb{N}}$  in the domain to the set

$$\left\{ f \in 2^\mathbb{N} : \forall n (([S_n] \neq \emptyset \rightarrow f(n) = 0) \wedge ([T_n] \neq \emptyset \rightarrow f(n) = 1)) \right\}.$$

One can introduce a similar multivalued function by directly using the space  $\Sigma_1^1(\mathbb{N}) \times \Sigma_1^1(\mathbb{N})$  instead of  $(\mathbf{Tr} \times \mathbf{Tr})^\mathbb{N}$  without affecting the Weihrauch degree.

**Definition 3.9** ( $\Delta_1^1$ -Comprehension). Let  $\Delta_1^1\text{-CA} : \subseteq (\mathbf{Tr} \times \mathbf{Tr})^\mathbb{N} \rightarrow 2^\mathbb{N}$  be the restriction of  $\Sigma_1^1\text{-Sep}$  to the set  $\{(S_n, T_n)_{n \in \mathbb{N}} : \forall n ([S_n] = \emptyset \leftrightarrow [T_n] \neq \emptyset)\}$ . Let  $\Delta_1^1\text{-CA}^-$  be the restriction of  $\Delta_1^1\text{-CA}$  to the set  $\{(S_n, T_n)_{n \in \mathbb{N}} : \forall n |[S_n]| + |[T_n]| = 1\}$ .

**Definition 3.10** (Weak  $\Sigma_1^1$ -Comprehension). Let  $\Sigma_1^1\text{-CA}^- : \subseteq \mathbf{Tr}^\mathbb{N} \rightarrow 2^\mathbb{N}$  be the function with domain  $\text{dom}(\Sigma_1^1\text{-CA}^-) = \{(T_n)_{n \in \mathbb{N}} : \forall n |[T_n]| \leq 1\}$  and that maps  $(T_n)_{n \in \mathbb{N}}$  to the unique  $f \in 2^\mathbb{N}$  such that  $f(n) = 1 \leftrightarrow |[T_n]| = 1$  for all  $n \in \mathbb{N}$ .

**Theorem 3.11.** The following are strongly Weihrauch equivalent:

1.  $UC_{\mathbb{N}^\mathbb{N}}$
2.  $\Sigma_1^1\text{-UC}_{\mathbb{N}^\mathbb{N}}$
3.  $\Sigma_1^1\text{-Sep}$
4.  $\Delta_1^1\text{-CA}$
5.  $\Delta_1^1\text{-CA}^-$
6.  $\Sigma_1^1\text{-CA}^-$

*Proof.* ( $\Sigma_1^1\text{-UC}_{\mathbb{N}^\mathbb{N}} \leq_{sW} UC_{\mathbb{N}^\mathbb{N}}$ ) This follows from the proof of  $\lim^\dagger \equiv_W UC_{\mathbb{N}^\mathbb{N}}$  given in [37]. An alternative proof can be obtained by noting that the proof of  $UC_{\mathbb{N}^\mathbb{N}} \leq_{sW} \Delta_1^1\text{-CA}^-$  given below is readily adapted to show that  $\Sigma_1^1\text{-UC}_{\mathbb{N}^\mathbb{N}} \leq_{sW} \Delta_1^1\text{-CA}$  instead, and use the reductions below.

$(UC_{\mathbb{N}^\mathbb{N}} \leq_{sW} \Sigma_1^1\text{-UC}_{\mathbb{N}^\mathbb{N}})$  Trivial, as  $\text{id} : \Pi_1^0(\mathbb{N}^\mathbb{N}) \rightarrow \Sigma_1^1(\mathbb{N}^\mathbb{N})$  is computable by Proposition 2.3(4).

$(\Sigma_1^1\text{-Sep} \leq_{sW} UC_{\mathbb{N}^\mathbb{N}})$  By [37, Proposition 62 & Lemma 79]. An alternative proof can be obtained by combining Lemmata 5.6 and 5.7 below.

$(\Delta_1^1\text{-CA} \leq_{sW} \Sigma_1^1\text{-Sep})$  The former is a restriction of the latter.

$(\Delta_1^1\text{-CA}^- \leq_{sW} \Delta_1^1\text{-CA})$  The former is a restriction of the latter.

( $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \leq_{\text{sW}} \Delta_1^1\text{-CA}^-$ ) Let  $\{f\}$  be a singleton of  $\mathbb{N}^{\mathbb{N}}$  given via some tree  $T$  such that  $[T] = \{f\}$ . From  $T$  we compute the double-sequence of trees  $(T_t^0, T_t^1)_{t \in \mathbb{N}^{<\mathbb{N}}}$  such that: for all  $t \in \mathbb{N}^{<\mathbb{N}}$ ,

- $T_t^0 = \{s \in T : t \sqsubseteq s \vee s \sqsubseteq t\}$ ,
- $T_t^1 = \{s \in T : t \not\sqsubseteq s\}$ .

Note that, for all  $t \in \mathbb{N}^{<\mathbb{N}}$ , exactly one between  $T_t^0$  and  $T_t^1$  is ill-founded. In fact, if  $t \sqsubseteq f$  then  $f \in [T_t^0]$  and, since  $T$  has only one path,  $T_t^1$  is well-founded. Otherwise, if  $t \not\sqsubseteq f$  then  $f \in [T_t^1]$  and  $[T_t^0] = \emptyset$ . Hence, we even have that for all  $t \in \mathbb{N}^{<\mathbb{N}}$ ,  $|[T_t^0]| + |[T_t^1]| = 1$ .

Consider now  $g = \Delta_1^1\text{-CA}^-((T_t^0, T_t^1)_{t \in \mathbb{N}^{<\mathbb{N}}})$ . For all  $t \in \mathbb{N}^{<\mathbb{N}}$ ,  $g(t) = 0 \iff [T_t^0] \neq \emptyset \iff t \sqsubseteq f$ . Therefore, given  $n \in \mathbb{N}$ , to compute  $f(n)$  it suffices to wait for the first  $t \in \mathbb{N}^{n+1}$  such that  $g(t) = 0$  and then put  $f(n) = t(n)$ . This concludes the proof.

( $\Delta_1^1\text{-CA}^- \leq_{\text{sW}} \Sigma_1^1\text{-CA}^-$ ) For every  $(T_n^0, T_n^1)_{n \in \mathbb{N}} \in \text{dom}(\Delta_1^1\text{-CA}^-)$  we have that  $\Delta_1^1\text{-CA}^-((T_n^0, T_n^1)_{n \in \mathbb{N}}) = \Sigma_1^1\text{-CA}^-((T_n^1)_{n \in \mathbb{N}})$ .

( $\Sigma_1^1\text{-CA}^- \leq_{\text{sW}} \Sigma_1^1\text{-UC}_{\mathbb{N}^{\mathbb{N}}}$ ) Let  $(T_n)_{n \in \mathbb{N}}$  be a sequence of trees in  $\text{dom}(\Sigma_1^1\text{-CA}^-)$ . We claim that using  $\Sigma_1^1\text{-UC}_{\mathbb{N}^{\mathbb{N}}}$  we are able to compute  $f \in 2^{\mathbb{N}}$  such that:

$$\forall n(f(n) = 1 \leftrightarrow |[T_n]| = 1). \quad (1)$$

In fact, (1) is equivalent to

$$\forall n[(f(n) = 0 \vee \exists g(g \in [T_n])) \wedge (\neg \exists! g(g \in [T_n]) \vee f(n) = 1)],$$

which in turn is equivalent to

$$\forall n[\exists g(f(n) = 0 \vee g \in [T_n]) \wedge \neg \exists! g(g \in [T_n] \wedge f(n) = 0)]. \quad (2)$$

Now, for each  $n$ ,  $\{(g, f) \in \mathbb{N}^{\mathbb{N}} \times \mathbb{N}^{\mathbb{N}} : f(n) = 0 \vee g \in [T_n]\}$  is a computable closed subset of  $\mathbb{N}^{\mathbb{N}} \times \mathbb{N}^{\mathbb{N}}$ , which entails that  $\{f \in \mathbb{N}^{\mathbb{N}} : \exists g(f(n) = 0 \vee g \in [T_n])\}$  is a computable  $\Sigma_1^1(\mathbb{N}^{\mathbb{N}})$  set for each  $n \in \mathbb{N}$ . Furthermore, for each  $n \in \mathbb{N}$ ,  $\{(g, f) \in \mathbb{N}^{\mathbb{N}} \times \mathbb{N}^{\mathbb{N}} : g \in [T_n] \wedge f(n) = 0\}$  is also a computable closed set which, guarantees that  $\{f \in \mathbb{N}^{\mathbb{N}} : \neg \exists! g(g \in [T_n] \wedge f(n) = 0)\}$  is computable as a  $\Sigma_1^1(\mathbb{N}^{\mathbb{N}})$  set by Proposition 2.3(7).

Finally, since the operations of finite and countable intersection of  $\Sigma_1^1$  sets are computable, we are able to build a name (by Proposition 2.3(2)) for the  $\Sigma_1^1(\mathbb{N}^{\mathbb{N}})$  singleton

$$\left\{ f \in 2^{\mathbb{N}} : \forall n[\exists g(f(n) = 0 \vee g \in [T_n]) \wedge \neg \exists! g(g \in [T_n] \wedge f(n) = 0)] \right\}.$$

Clearly, applying  $\Sigma_1^1\text{-UC}_{\mathbb{N}^{\mathbb{N}}}$  to such set we obtain the unique  $f$  satisfying (1), which is exactly  $\Sigma_1^1\text{-CA}^-((T_n)_n)$ .  $\square$

## Arithmetical transfinite recursion

As mentioned above, the operation  $\lim^\dagger$  from [37] is the ordinal-iteration of the map  $\lim$ . Here, we will explore a direct encoding of arithmetical transfinite recursion as a Weihrauch degree, and give another proof of its equivalence with  $\text{UC}_{\mathbb{N}^{\mathbb{N}}}$ . Let us fix an effective enumeration  $\langle \phi_n : n \in \mathbb{N} \rangle$  of all the computable functions  $\phi : \subseteq \mathbb{N}^{\mathbb{N}} \rightarrow \mathbb{N}^{\mathbb{N}}$ . Note that  $\widehat{\text{LPO}}^{(k)}$  is a complete  $\Sigma_{k+2}^0$ -computable function, and thus one can think of  $\theta_n^k = \widehat{\text{LPO}}^{(k)} \circ \phi_n$  as the  $n^{\text{th}}$   $\Sigma_{k+2}^0$ -computable function. Instead, we could have used the  $n^{\text{th}}$   $\Sigma_{k+2}^0$  formula to define an equivalent notion.

**Definition 3.12** (Arithmetical transfinite recursion). Let  $\text{ATR} : \subseteq 2^{\mathbb{N}} \times \mathbf{WO} \times \mathbb{N}^2 \rightarrow 2^{\mathbb{N}}$  be the function which maps each  $(Z, X, (k, n)) \in 2^{\mathbb{N}} \times \mathbf{WO} \times \mathbb{N}^2$  to the set  $Y \in 2^{\mathbb{N}}$  such that, for all  $(y, j) \in \mathbb{N}^2$ ,

$$(y, j) \in Y \leftrightarrow j \in X \wedge y \in \theta_n^k(Y^j \oplus Z),$$

where  $Y^j = \{ \langle y, i \rangle \in Y : i <_X j \}$ .

Compare Definition 3.12 with  $\text{ATR}_0$  in reverse mathematics, cf. [41, Definition V.2.4]. Note that our  $\text{ATR}$  is a *single-valued* function since, as mentioned in the first remark in this section, our  $X$  is truly well ordered, and therefore, we do not need to consider pseudo-hierarchies.

**Theorem 3.13.**  $\text{ATR} \equiv_{\text{sW}} \text{UC}_{\mathbb{N}^{\mathbb{N}}}$ .

*Proof.* By Lemmata 3.15, 3.16 below and Theorem 3.11.  $\square$

**Lemma 3.14.** Let  $X$  be a computable metric space. Then the function  $F : \bigsqcup_k \Pi_k^0(\mathbb{N}^{\mathbb{N}} \times X) \rightarrow \Sigma_1^1(X)$  defined by

$$B \mapsto A = \left\{ x \in X : \exists g \in \mathbb{N}^{\mathbb{N}} (g, x) \in B \right\},$$

is computable.

*Proof.* It suffices to note that the inductive argument used in the proof of Proposition 2.3(5) is uniform in  $k$ .  $\square$

The following is an analog of the classical reverse mathematical fact [41, Theorem V.5.1].

**Lemma 3.15.**  $\text{ATR} \leq_{\text{sW}} \Sigma_1^1\text{-Sep}$ .

*Proof.* It is easy to see that  $\Sigma_1^1\text{-Sep}$  is a cylinder and hence it suffices to show  $\text{ATR} \leq_{\text{W}} \Sigma_1^1\text{-Sep}$ . Given  $(Z, X, \langle k, n \rangle) \in 2^{\mathbb{N}} \times \mathbf{WO} \times \mathbb{N}^2$ , we want to compute  $\text{ATR}(Z, X, \langle k, n \rangle)$  as defined in Definition 3.12. For each  $j \in X$  and  $Y \in 2^{\mathbb{N}}$ , let us consider the following formula:

$$H(Y, j) \equiv \forall \langle y, i \rangle \in \mathbb{N}^2 [\langle y, i \rangle \in Y \iff i <_X j \wedge y \in \theta_n^k(Y^i \oplus Z)],$$

Essentially,  $H(Y, j)$  says that  $Y$  is the set  $\{ \langle y, i \rangle \in \text{ATR}(Z, X, \langle k, n \rangle) : i <_X j \}$ . Using now  $H$ , we define the following two formulas for each  $j, z \in \mathbb{N}$ :

$$\begin{aligned} \varphi_0(j, z) &\equiv j \in X \wedge \exists Y \in 2^{\mathbb{N}} [H(Y, j) \wedge z \in \theta_n^k(Y^j \oplus Z)], \\ \varphi_1(j, z) &\equiv j \in X \wedge \exists Y \in 2^{\mathbb{N}} [H(Y, j) \wedge z \notin \theta_n^k(Y^j \oplus Z)]. \end{aligned}$$

Note that, for each  $j \in X$  and  $z \in \mathbb{N}$  we have  $\varphi_0(j, z) \iff \langle z, j \rangle \in \text{ATR}(Z, X, \langle k, n \rangle)$ .

Using the function  $F$  defined in Lemma 3.14 and the closure properties of Proposition 2.3, we are able to compute two names for the  $\Sigma_1^1(\mathbb{N}^2)$ -sets  $A_0$  and  $A_1$  corresponding to the formulas  $\varphi_0$  and  $\varphi_1$ . Note that in this case the use of  $F$  is required and we cannot appeal to Proposition 2.3(5) because  $k$  is not fixed but is given with the input. It is easy to see that  $A_0$  and  $A_1$  are disjoint; hence one can ask  $\Sigma_1^1\text{-Sep}$  to give us  $f$  separating  $A_0$  from  $A_1$ , which is clearly a solution of  $\text{ATR}(Z, X, \langle k, n \rangle)$ . Here are the details:

Since the names for  $A_0$  and  $A_1$  are  $\Pi_1^0(\mathbb{N}^{\mathbb{N}} \times \mathbb{N}^2)$ -names, it is not difficult to see that we can build a double sequence of trees  $(T_{\langle j, z \rangle}^0, T_{\langle j, z \rangle}^1)_{j, z \in \mathbb{N}}$  such that, for each  $j \in \mathbb{N}$  and  $z \in \mathbb{N}$ ,

- $\langle j, z \rangle \in A_0 \iff [T_{\langle j, z \rangle}^0] \neq \emptyset$ ,

- $\langle j, z \rangle \in A_1 \iff [T_{\langle j, z \rangle}^1] \neq \emptyset$ .

Note that, if  $j \notin X$  then for each  $z \in \mathbb{N}$ ,  $\neg\varphi_0(j, z)$  and  $\neg\varphi_1(j, z)$ , which means that  $[T_{\langle j, z \rangle}^0] = [T_{\langle j, z \rangle}^1] = \emptyset$ . If instead  $j \in X$  we have, for each  $z \in \mathbb{N}$ ,  $\varphi_0(j, z) \iff \neg\varphi_1(j, z)$  which implies  $[T_{\langle j, z \rangle}^0] \neq \emptyset \iff [T_{\langle j, z \rangle}^1] = \emptyset$ . Therefore the double-sequence of trees  $(T_{\langle j, z \rangle}^0, T_{\langle j, z \rangle}^1)_{j, z \in \mathbb{N}}$  belongs to the domain of  $\Sigma_1^1$ -Sep. So let  $f \in \Sigma_1^1\text{-Sep}(T_{\langle j, z \rangle}^0, T_{\langle j, z \rangle}^1)_{j, z \in \mathbb{N}}$ . Now we have, for each  $j \in X$  and  $z \in \mathbb{N}$ ,  $f(j, z) = 0 \iff [T_{\langle j, z \rangle}^0] \neq \emptyset \iff \varphi_0(j, z) \iff \langle z, j \rangle \in \text{ATR}(Z, X, \langle k, n \rangle)$ , i.e. we are able to compute  $\text{ATR}(Z, X, \langle k, n \rangle) \in 2^\mathbb{N}$  using  $f$ .

Note that we are using the original input to test whether  $j \in X$ .  $\square$

**Lemma 3.16.**  $\Delta_1^1\text{-CA} \leq_{\text{sW}} \text{ATR}$ .

*Proof.* Let  $(T_n^0, T_n^1)_{n \in \mathbb{N}} \in \text{dom}(\Delta_1^1\text{-CA})$ , we want to compute  $f \in 2^\mathbb{N}$  such that, for all  $n \in \mathbb{N}$ ,  $f(n) = 0 \iff [T_n^0] \neq \emptyset$ . In order to apply ATR we have to specify a set parameter  $Z$ , a well ordering  $X$  and an arithmetical formula. The role of  $Z$  in this case will be played by  $(T_n^0, T_n^1)_{n \in \mathbb{N}}$ . The well ordering  $X$  is obtained as  $\sum_{n \in \mathbb{N}} (\text{KB}(T_n^0) * \text{KB}(T_n^1)) + 1$  (which is a well ordering by Lemma 2.7(1)).

It remains to specify an arithmetical formula  $\varphi(y, Y^j \oplus Z)$  which describes what to do at each step of the recursion. We read both  $Y^j$  and  $Z$  as coding a sequence of pairs of trees. The idea is to eliminate at each step the leaves of all the trees in the sequence. Thus,  $\varphi(y, Y^j \oplus Z)$  holds if either  $Y^j = \emptyset$  and  $y$  codes a vertex with a child in  $Z$ , or  $y$  codes a vertex with a child in each tree from  $Y^j$ . This is easily verified to be an arithmetical formula, and hence can be coded as some  $\theta_n^k$ .<sup>3</sup>

Finally, consider  $Y = \text{ATR}((T_n^0, T_n^1)_n, X, \langle k, n \rangle)$ , which is the set we obtain after repeating, along the well ordering  $X$ , the procedure of eliminating leaves from the trees  $T_n^0$  and  $T_n^1$ . Now, let fix  $n$  and consider  $i \in \{0, 1\}$  such that  $T_n^i$  is well founded. Note that, in order to eliminate all the tree  $T_n^i$ , the recursion should be done at least over the ordinal rank( $T_n^i$ ). In our case, the recursion is done over  $X$  whose order type is greater than the order type of  $\text{KB}(T_n^i)$  which in turn is greater than  $\text{rank}(T_n^i)$ , cf. Lemma 2.7(2). This means that  $Y$  does not contain any element of the tree  $T_n^i$ . This argument applies to each well founded tree in the sequence  $(T_n^0, T_n^1)_n$ , so we can know whether a tree in the sequence has a path or not simply by checking if its root is in  $Y$ . It is easy to see that this allows us to compute  $\Delta_1^1\text{-CA}((T_n^0, T_n^1)_{n \in \mathbb{N}})$ .  $\square$

## 4 $\Sigma_1^1$ -weak König's lemma

### 4.1 $\Sigma_1^1$ versus $\Pi_1^1$

In this section, we focus on the following contrast between reverse mathematics and the Weihrauch lattice regarding  $\Sigma_1^1$  and  $\Pi_1^1$ -separation: On the one hand, in reverse mathematics, we have

$$\Pi_1^1\text{-SEP}_0 < \Sigma_1^1\text{-SEP}_0 \tag{3}$$

where  $A < B$  indicates  $\text{RCA}_0 \vdash B \rightarrow A$ , but  $\text{RCA}_0 \not\vdash A \rightarrow B$ . On the other hand, in the Weihrauch lattice, we have

$$\Sigma_1^1\text{-Sep} <_W \Pi_1^1\text{-Sep}. \tag{4}$$

---

<sup>3</sup>Similar ideas are found in the investigation of the Weihrauch degree of the *pruning derivative* of a tree in [33].

The former inequality (3) was proven by Montalbán [30] using Steel's tagged tree forcing. The latter inequality (4) follows from the well-known fact in descriptive set theory that  $\Sigma_1^1$  has the  $\Delta_1^1$ -separation property, while  $\Pi_1^1$  does not (see also Lemma 4.4). It is not hard to explain the cause of the contrast between (3) and (4), namely the Spector-Gandy phenomenon.

Let  $\mathcal{M}$  be an  $\omega$ -model, and let  $(\Sigma_1^1)^{\mathcal{M}}$  be the collection of all subsets of  $\omega$  which are  $\Sigma_1^1$ -definable within  $\mathcal{M}$ , that is,  $(\Sigma_1^1)^{\mathcal{M}} = \{\{n \in \omega : \mathcal{M} \models \varphi(n)\} : \varphi \in \Sigma_1^1\}$ . We define  $(\Pi_1^1)^{\mathcal{M}}$  analogously. Consider the  $\omega$ -model  $\text{HYP}$  consisting of all hyperarithmetical reals. The Spector-Gandy theorem (cf. [40, Theorem III.3.5 + Lemma III.3.1] or [41, Theorems VIII.3.20 + VIII.3.21]) implies that

$$(\Sigma_1^1)^{\text{HYP}} = \Pi_1^1, \text{ and } (\Pi_1^1)^{\text{HYP}} = \Sigma_1^1.$$

The roles of  $\Sigma_1^1$  and  $\Pi_1^1$  are interchanged! We should always be careful in this role-exchange phenomenon of  $\Sigma_1^1$  and  $\Pi_1^1$  when comparing reverse math and computability theory. Of course, the notion of a  $\beta$ -model solves this role-exchange problem. To be precise, a  $\beta$ -model (see [41, Section VII]) is an  $\omega$ -model  $\mathcal{M}$  satisfying the following condition:

$$(\Sigma_1^1)^{\mathcal{M}} = \Sigma_1^1, \text{ and } (\Pi_1^1)^{\mathcal{M}} = \Pi_1^1.$$

However, the notion of a  $\beta$ -model is obviously related to closed choice  $C_{\mathbb{N}^{\mathbb{N}}}$ : An  $\omega$ -model  $\mathcal{M}$  is a  $\beta$ -model iff, for any  $Z \in \mathcal{M}$  and non-empty  $\Pi_1^0(Z)$  set  $P \subseteq \mathbb{N}^{\mathbb{N}}$ , some  $\alpha \in P$  belongs to  $\mathcal{M}$ . Therefore, when studying principles weaker than  $C_{\mathbb{N}^{\mathbb{N}}}$ , we cannot work within the  $\beta$ -models.

Now, how should we interpret the reverse-mathematical  $\Sigma_1^1$ -separation principle in our real universe? The right answer may not exist. It may be  $\Pi_1^1$ -Sep or may be  $\Sigma_1^1$ -Sep.

We have already examined the strength of the  $\Sigma_1^1$ -separation principle  $\Sigma_1^1$ -Sep. In this section, we will investigate the  $\Pi_1^1$ -separation principle,  $\Pi_1^1$ -Sep, in the Weihrauch lattice. In reverse mathematics, Montalbán [30] showed that the strength of the  $\Pi_1^1$ -separation principle is strictly between  $\Delta_1^1$ -CA<sub>0</sub> and ATR<sub>0</sub> (⁴):

$$\Delta_1^1\text{-CA}_0 < \Pi_1^1\text{-SEP}_0 < \text{ATR}_0 \equiv \Sigma_1^1\text{-SEP}_0.$$

Moreover,  $\Delta_1^1$ -CA<sub>0</sub> and  $\Pi_1^1$ -SEP<sub>0</sub> are *theories of hyperarithmetic analysis*, that is, for every  $Z \subseteq \omega$ , HYP( $Z$ ) is the least  $\omega$ -model of that theory containing  $Z$ . On the other hand, HYP  $\not\models$  ATR<sub>0</sub>. In contrast, we will see the following:

$$\text{UC}_{\mathbb{N}^{\mathbb{N}}} \equiv_W \Delta_1^1\text{-CA} \equiv_W \text{ATR} \equiv_W \Sigma_1^1\text{-Sep} <_W \Pi_1^1\text{-Sep} <_W C_{\mathbb{N}^{\mathbb{N}}}.$$

## 4.2 The strength of $\Sigma_1^1$ -weak König's lemma

The principle of  $\Pi_1^0$ -separation was studied already in the precursor works by Weihrauch [43], and Weak König's Lemma (aka closed choice on Cantor space) was a focus in the earliest work on Weihrauch reducibility in the modern understanding [20, 7, 5]. Here, we explore their higher-level analogues.

Let  $\Pi_1^1$ -Sep be the following partial multivalued function: Given  $\Pi_1^1$ -codes of sets  $A, B \subseteq \mathbb{N}$ , if  $A$  and  $B$  are disjoint, then return a set  $C \subseteq \mathbb{N}$  separating  $A$  from  $B$ , that is,  $A \subseteq C$  and  $B \cap C = \emptyset$ . To be more precise:

**Definition 4.1.** Let  $\Pi_1^1$ -Sep  $\subset \Pi_1^1(\mathbb{N}) \times \Pi_1^1(\mathbb{N}) \Rightarrow 2^{\mathbb{N}}$  be such that  $C \in \Pi_1^1\text{-Sep}(A, B)$  iff  $C$  separates  $A$  from  $B$ , where  $(A, B) \in \text{dom}(\Pi_1^1\text{-Sep})$  iff  $A \cap B = \emptyset$ .

---

<sup>4</sup>Actually, Montalbán showed that  $\Pi_1^1$ -separation is strictly weaker than  $\Sigma_1^1$ -AC.

We also consider  $\Sigma_1^1$ -weak König's lemma  $\Sigma_1^1\text{-WKL}$ : Given a  $\Sigma_1^1$ -code of a set  $T \subseteq 2^{<\omega}$ , if  $T$  is an infinite binary tree, then return a path through  $T$ . Formally speaking:

**Definition 4.2.** Let  $\Sigma_1^1\text{-WKL} : \subseteq \Sigma_1^1(2^{<\omega}) \Rightarrow 2^{\mathbb{N}}$  be such that  $p \in \Sigma_1^1\text{-WKL}(T)$  iff  $p$  is an infinite path through  $T$ , where  $T \in \text{dom}(\Sigma_1^1\text{-WKL})$  iff  $T$  is an infinite binary tree.

While  $\Sigma_1^1\text{-WKL}$  appears as a  $\Sigma_1^1$ -version of closed choice on Cantor space, it is not equivalent to  $\Sigma_1^1$ -choice on  $2^{\mathbb{N}}$  (nor, equivalently, closed choice on  $\mathbb{N}^{\mathbb{N}}$ ). Instead, it is equivalent to the parallelization  $\widehat{\Sigma_1^1\text{-C}_2}$  of  $\Sigma_1^1$  choice on the discrete space  $\mathbf{2} = \{0, 1\}$ . We will show the following.

**Theorem 4.3.**  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} <_{\text{W}} \widehat{\Sigma_1^1\text{-C}_2} \equiv_{\text{W}} \Pi_1^1\text{-Sep} \equiv_{\text{W}} \Sigma_1^1\text{-WKL} <_{\text{W}} \widehat{\Sigma_1^1\text{-C}_{\mathbb{N}}} \leq_{\text{W}} \text{C}_{\mathbb{N}^{\mathbb{N}}}$ .

We will use the following fundamental notion in HYP-theory. A  $\Pi_1^1$ -norm on a  $\Pi_1^1$  set  $P \subseteq \mathbb{N}$  is a map  $\varphi : \mathbb{N} \rightarrow \omega_1^{CK} \cup \{\infty\}$  such that  $P = \{n : \varphi(n) < \infty\}$  and that the following relations  $\leq_{\varphi}$  and  $<_{\varphi}$  are  $\Pi_1^1$ :

$$\begin{aligned} a \leq_{\varphi} b &\iff \varphi(a) < \infty \text{ and } \varphi(a) \leq \varphi(b), \\ a <_{\varphi} b &\iff \varphi(a) < \infty \text{ and } \varphi(a) < \varphi(b). \end{aligned}$$

It is well-known that every  $\Pi_1^1$  set admits a  $\Pi_1^1$ -norm (in an effective manner): Consider a many-one reduction from a  $\Pi_1^1$  set  $P$  to the set WO of well orderings. We will explore the uniform complexity of this kind of stage comparison principle in Section 5.

One can easily separate unique choice on  $\mathbb{N}^{\mathbb{N}}$  and the  $\Pi_1^1$ -separation principle by considering the *diagonally non-hyperarithmetical* functions, which is a HYP version of  $\text{DNC}_2$  (known as diagonally noncomputable functions). A very basic fact in HYP-theory is the existence of a computable enumeration  $(\psi_e)_{e \in \mathbb{N}}$  of all partial  $\Pi_1^1$  functions on  $\mathbb{N}$ . For instance, let  $\psi_e$  be a standard  $\Pi_1^1$ -uniformization of the  $e^{th}$   $\Pi_1^1$  set  $P_e \subseteq \mathbb{N} \times \mathbb{N}$ , that is,  $\psi_e(n)$  is an element in the  $n^{th}$  section of  $P_e$  attaining the smallest  $\varphi$ -value if it exists, where  $\varphi$  is a  $\Pi_1^1$ -norm on  $P_e$ .

**Lemma 4.4.**  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} <_{\text{W}} \Pi_1^1\text{-Sep}$ .

*Proof.* To see that  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \leq_{\text{W}} \Pi_1^1\text{-Sep}$ , note that  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \equiv_{\text{W}} \Delta_1^1\text{-CA}$  by Theorem 3.11, and  $\Delta_1^1\text{-CA} \leq_{\text{W}} \Pi_1^1\text{-Sep}$  is straightforward. For the separation, let  $(\psi_e)_{e \in \mathbb{N}}$  be an enumeration of all partial  $\Pi_1^1$  functions on  $\mathbb{N}$  as above. For  $i < 2$ , consider  $P_i = \{e \in \mathbb{N} : \psi_e(e) \downarrow = i\}$ . Clearly  $P_i$  is  $\Pi_1^1$ , and  $P_0 \cap P_1 = \emptyset$ . It is easy to see that there is no  $\Delta_1^1$  set separating  $P_0$  and  $P_1$ .  $\square$

The proof of Lemma 4.4 motivates us to introduce the following multivalued function  $\Pi_1^1\text{-DNC}_2 : 2^{\mathbb{N}} \Rightarrow 2^{\mathbb{N}}$ : Given an oracle  $X$ , return a two-valued  $X$ -diagonally non-hyperarithmetical function  $f$ , that is,  $f \in \Pi_1^1\text{-DNC}_2(X)$  iff, whenever  $\psi_e^X(e) \downarrow$ ,  $f(e) \neq \psi_e^X(e)$ , where  $(\psi_e^X)_{e \in \mathbb{N}}$  is a canonical enumeration of all partial  $\Pi_1^1(X)$  functions on  $\mathbb{N}$ . The following is an analog of the well-known fact that every  $\text{DNC}_2$ -function has a PA-degree.

**Proposition 4.5.**  $\Pi_1^1\text{-Sep} \equiv_{\text{W}} \Pi_1^1\text{-DNC}_2$ .

*Proof.* Let  $P_0$  and  $P_1$  be disjoint  $\Pi_1^1$  sets. Clearly there is  $e$  such that  $n \in P_i$  iff  $\psi_e(n) \downarrow = i$ . By the recursion theorem, one can uniformly find a computable function  $r$  such that  $\psi_{r(n)}(r(n)) \simeq \psi_e(n)$ . Let  $f$  be a diagonally non-hyperarithmetical function. If  $f(r(n)) = i$  then  $\psi_{r(n)}(r(n)) \simeq \psi_e(n) \neq i$ , which implies  $n \notin P_i$ . Therefore,  $S = \{n : f(r(n)) = 1\}$  separates  $P_0$  from  $P_1$ . This argument is easily relativizable uniformly. The converse direction is also clear.  $\square$

Using a  $\Pi_1^1$ -norm, one can show  $\Sigma_1^1\text{-WKL} \equiv_{\text{W}} \Pi_1^1\text{-Sep}$  by modifying the usual proof of the well-known equivalence between  $\text{WKL}$  and  $\Sigma_1^0\text{-Sep}$ .

**Lemma 4.6.**  $\Sigma_1^1\text{-WKL} \equiv_W \Pi_1^1\text{-Sep} \equiv_W \widehat{\Sigma_1^1\text{-C}_2}$ .

*Proof.* By a straightforward modification of the usual proof of  $\Sigma_1^0\text{-Sep} \equiv_W \widehat{C_2}$ , it is easy to see that  $\Pi_1^1\text{-Sep} \equiv_W \widehat{\Sigma_1^1\text{-C}_2}$  holds. It is also clear that  $\Pi_1^1\text{-Sep} \leq_W \Sigma_1^1\text{-WKL}$ . Thus, it suffices to show that  $\Sigma_1^1\text{-WKL} \leq_W \Pi_1^1\text{-Sep}$ .

Given a  $\Sigma_1^1$ -tree  $T \subseteq 2^{<\omega}$ , let  $\text{Ext}_T \subseteq 2^{<\omega}$  be the set of all extendible nodes of  $T$ . Clearly, its complement  $\neg\text{Ext}_T = 2^{<\omega} \setminus \text{Ext}_T$  is  $\Pi_1^1$ , and thus admits a  $\Pi_1^1$ -norm  $\varphi$  (we need to get  $\varphi$  in a uniform way, but it is straightforward). Consider the  $\Pi_1^1$  set  $P_i = \{\sigma : \sigma^\frown i <_\varphi \sigma^\frown (1-i)\}$  for each  $i < 2$ . Obviously,  $P_0 \cap P_1 = \emptyset$ . We claim that

$$\sigma \in \text{Ext}_T \text{ and } \sigma \notin P_j \implies \sigma^\frown j \in \text{Ext}_T.$$

If  $\sigma \notin P_j$  then  $\sigma^\frown j \not<_\varphi \sigma^\frown (1-j)$ , that is, either  $\varphi(\sigma^\frown j) = \infty$  or  $\varphi(\sigma^\frown (1-j)) \leq \varphi(\sigma^\frown j)$  holds. If the former holds then we must have  $\sigma^\frown j \in \text{Ext}_T$ . If  $\varphi(\sigma^\frown j) < \infty$ , then we must have  $\varphi(\sigma^\frown (1-j)) = \infty$  since  $\sigma \in \text{Ext}_T$  implies that  $\sigma^\frown i \in \text{Ext}_T$  for some  $i < 2$ . By the latter condition,  $\infty = \varphi(\sigma^\frown (1-j)) \leq \varphi(\sigma^\frown j)$ ; hence  $\varphi(\sigma^\frown j)$  must be  $\infty$ . In any case, we have  $\varphi(\sigma^\frown j) = \infty$ , which means that  $\sigma^\frown j \in \text{Ext}_T$ . This verifies the above claim.

Let  $S$  be such that  $P_0 \subseteq S$  and  $S \cap P_1 = \emptyset$ . Let  $\sigma_0$  be the empty string, and put  $\sigma_{n+1} = \sigma_n \wedge S(\sigma_n)$ . Then, by the above claim, we have  $\sigma_n \in \text{Ext}_T$  for any  $n$ , and therefore  $\bigcup_n \sigma_n \in [T]$ . One can easily relativize this argument uniformly.  $\square$

**Lemma 4.7.**  $\Sigma_1^1\text{-WKL} <_W \widehat{\Sigma_1^1\text{-C}_\mathbb{N}}$ .

*Proof.* By Lemma 4.6, we have  $\Sigma_1^1\text{-WKL} \leq_W \widehat{\Sigma_1^1\text{-C}_\mathbb{N}}$ . It remains to show that  $\widehat{\Sigma_1^1\text{-C}_\mathbb{N}} \not\leq_W \Sigma_1^1\text{-WKL}$ . It is easy to see that  $\Sigma_1^1\text{-WKL}$  is a cylinder, and hence it suffices to show that  $\widehat{\Sigma_1^1\text{-C}_\mathbb{N}} \not\leq_{sW} \Sigma_1^1\text{-WKL}$ .

We first show the following claim: Let  $T \subseteq 2^{<\omega}$  be a  $\Sigma_1^1$  tree, and  $\Phi$  a Turing functional such that for every  $x \in [T]$ ,  $\Phi^x$  is total. Then there exists a  $\Delta_1^1$  function  $h : \mathbb{N} \rightarrow \mathbb{N}$  majorizing  $n \mapsto \Phi^x(n)$  for every  $x \in [T]$ .

Let  $g : \mathbb{N} \rightarrow \mathbb{N}$  be a function such that for any  $n$ , if  $|\sigma| = g(n)$  then either  $\sigma \notin \text{Ext}_T$  or  $\Phi^\sigma(n) \downarrow$ . This condition is clearly  $\Pi_1^1$ , and by compactness,  $g$  is total. Hence,  $g$  is a total  $\Pi_1^1$  function, and thus actually  $\Delta_1^1$ . Then define  $h(n) = \max\{\Phi^\sigma(n) : |\sigma| = g(n) \text{ and } \Phi^\sigma(n) \downarrow\}$ . Clearly  $h$  is  $\Delta_1^1$  and  $\Phi^x(n) \leq h(n)$  for any  $x \in [T]$ . This verifies the claim.

Let  $(\psi_e)_{e \in \omega}$  be a computable enumeration of partial  $\Pi_1^1$  functions on  $\mathbb{N}$ . Let  $S_e$  be the set of all  $k$  such that

$$(\forall n \leq e)(\psi_n(e) \downarrow \implies \psi_n(e) < k).$$

Clearly  $S_e$  is  $\Sigma_1^1$  and cofinite. Then every element of  $S = \prod_e S_e$  dominates all  $\Delta_1^1$  functions. If  $\widehat{\Sigma_1^1\text{-C}_\mathbb{N}} \leq_{sW} \Sigma_1^1\text{-WKL}$  then we must have a  $\Sigma_1^1$ -tree  $T \subseteq 2^{<\omega}$  whose paths compute uniformly an element of  $S$ , which is impossible by the above claim.  $\square$

Recall that  $A \star B$  denotes the sequential composition of  $A$  and  $B$ , cf. [15], that is, a function attaining the greatest Weihrauch degree among  $\{g \circ f : g \leq_W A \text{ and } f \leq_W B\}$ .

**Proposition 4.8.**  $\Sigma_1^1\text{-WKL} \star \Sigma_1^1\text{-WKL} \equiv_W \Sigma_1^1\text{-WKL}$ .

*Proof.* This is a modification of the independent choice theorem from [5]. We can assume that the inputs to  $\Sigma_1^1\text{-WKL} \star \Sigma_1^1\text{-WKL}$  are a computable function  $f$ ,  $z \in 2^\mathbb{N}$  as well as (relativizable)  $\Sigma_1^1$  trees  $S$  and  $T$ . Then,  $\{x \oplus y : x \in [S^z] \text{ and } y \in [T^{f(z,x)}]\}$  is a  $\Sigma_1^1$  closed set, and any of its elements is a solution to  $\Sigma_1^1\text{-WKL} \star \Sigma_1^1\text{-WKL}$ .  $\square$

There is a natural principle between  $UC_{\mathbb{N}^\mathbb{N}}$  and  $\Sigma_1^1\text{-WKL}$ . Let us define  $\Sigma_1^1$ -weak weak König's lemma  $\Sigma_1^1\text{-WWKL}$  as follows: Given a  $\Sigma_1^1$  set  $T \subseteq 2^{<\omega}$ , if  $T$  is an infinite binary tree and if  $[T]$  has a positive measure, then return a path through  $T$ . This is in analogy to the usual weak weak König's lemma, whose Weihrauch degree was studied in [14, 8, 10].

Note that Hjorth and Nies (see [32, Chapter 9.2]) showed that there is a  $\Sigma_1^1$ -closed set consisting of  $\Pi_1^1$ -Martin-Löf random reals. Indeed, the proof shows that  $\Pi_1^1\text{-MLR}$  is Weihrauch reducible to  $\Sigma_1^1\text{-WWKL}$ , where  $\Pi_1^1\text{-MLR}$  is a multivalued functions representing  $\Pi_1^1$ -Martin-Löf randomness, which is introduced in a straightforward manner. We also have  $WKL \not\leq_W \Sigma_1^1\text{-WWKL}$  since the Turing upward closure of any nontrivial separating class has measure zero (cf. [24, Theorem 5.3]). We show that, even if we enhance  $\Sigma_1^1\text{-WWKL}$  by adding a hyperarithmetical power, its strength is strictly weaker than  $\Sigma_1^1\text{-WKL}$ :

**Theorem 4.9.**  $UC_{\mathbb{N}^\mathbb{N}} <_W UC_{\mathbb{N}^\mathbb{N}} \star \Sigma_1^1\text{-WWKL} <_W \Sigma_1^1\text{-WKL}$ .

*Proof.* The inequality  $UC_{\mathbb{N}^\mathbb{N}} <_W UC_{\mathbb{N}^\mathbb{N}} \star \Sigma_1^1\text{-WWKL}$  is obvious since no  $\Pi_1^1$ -Martin-Löf random real is hyperarithmetic. Moreover, by Proposition 4.8, we have  $UC_{\mathbb{N}^\mathbb{N}} \star \Sigma_1^1\text{-WWKL} \leq_W \Sigma_1^1\text{-WKL}$ . Suppose for the sake of contradiction that  $\Sigma_1^1\text{-WKL} \leq_W UC_{\mathbb{N}^\mathbb{N}} \star \Sigma_1^1\text{-WWKL}$ . Then, for any  $\Sigma_1^1$  closed set  $S$ , there are a  $\Sigma_1^1$  closed set  $P$  of positive measure and a  $\Pi_1^1$  function  $f : P \rightarrow S$ , so that  $f(x) \leq_h x$  for any  $x \in P$ .

In particular, assume that  $S$  is the set of all  $\Pi_1^1\text{-DNC}_2$  functions, and let  $P$  and  $f$  be as above. It is known that  $x$  is  $\Pi_1^1$ -random iff  $x$  is  $\Delta_1^1$ -random and  $\omega_1^{CK,x} = \omega_1^{CK}$  (see [32, Theorem 9.3.9]). Since there are conull many  $\Pi_1^1$ -random reals,  $Q = \{x \in P : \omega_1^{CK,x} = \omega_1^{CK}\}$  also has positive measure. Given  $x \in Q$ , there is an ordinal  $\alpha < \omega_1^{CK,x} = \omega_1^{CK}$  such that  $f(x) \leq_T x \oplus \emptyset^{(\alpha)}$  (cf. [16, Lemma 4.2] and [1, Section 2.3.2]). As in [24, Theorem 5.3], it is easy to see that the  $\emptyset^{(\alpha)}$ -Turing upward closure,  $S_\alpha = \{z : h \leq_T z \oplus \emptyset^{(\alpha)} \text{ for some } h \in S\}$ , of  $S$  has measure zero for any computable ordinal  $\alpha$ . Hence,  $\hat{S} = \bigcup\{S_\alpha : \alpha < \omega_1^{CK}\}$  is also null. Our previous argument shows that  $Q \subseteq \hat{S}$ , however  $\mu(\hat{S}) = 0$  contradicts  $\mu(Q) > 0$ .  $\square$

**Question 4.10** ([9]).  $\widehat{\Sigma_1^1\text{-C}_\mathbb{N}} <_W C_{\mathbb{N}^\mathbb{N}}$ ?

## 5 Comparability of well orderings

Two statements which are equivalent to  $ATR_0$  are comparability of well orderings and weak comparability of well orderings ([41, Theorem V.6.8] and [19]). These involve two kinds of effective witnesses that one well ordering is shorter than another: strong comparison maps and order preserving maps.

**Definition 5.1.** If  $X, Y \in \mathbf{WO}$  then we say that  $f : \mathbb{N} \rightarrow \mathbb{N}$  is a *strong comparison map* between  $X$  and  $Y$ , in symbols  $f : X \leq_s Y$ , if the following conditions hold:

- $\forall n(n \notin X \rightarrow f(n) = 0)$ ,
- $\forall n, m \in X(n \leq_X m \leftrightarrow f(n) \leq_Y f(m))$ ,

- $\forall n \in X \forall k \in Y (k \leq_Y f(n) \rightarrow \exists m \in X f(m) = k)$ .

In other words,  $f$  is an order embedding of  $X$  into  $Y$  whose image is an initial segment of  $Y$ .

**Definition 5.2** (Comparability of well orderings). Let  $\text{CWO} : \mathbf{WO} \times \mathbf{WO} \rightarrow \mathbb{N}^{\mathbb{N}}$  be the function that maps any pair  $(X, Y)$  of countable well orderings to the unique  $f \in \mathbb{N}^{\mathbb{N}}$  such that  $f : X \leq_s Y$  or  $f : Y + 1 \leq_s X$ .

**Definition 5.3.** If  $X, Y \in \mathbf{LO}$  we say that  $f : \mathbb{N} \rightarrow \mathbb{N}$  is an *order preserving map* between  $X$  and  $Y$ , in symbols  $f : X \leq Y$ , if the following conditions hold:

- $\forall n (n \notin X \rightarrow f(n) = 0)$ ,
- $\forall n, m \in X (n \leq_X m \leftrightarrow f(n) \leq_Y f(m))$ ,

**Definition 5.4** (Weak comparability of well orderings). Let  $\text{WCWO} : \mathbf{WO} \times \mathbf{WO} \rightrightarrows \mathbb{N}^{\mathbb{N}}$  be the multivalued function that maps any pair  $(X, Y)$  of countable well orderings to the set  $\{f \in \mathbb{N}^{\mathbb{N}} : (f : X \leq Y) \vee (f : Y \leq X)\}$ .

The following classifies the Weihrauch degree of comparability of well orderings:

**Theorem 5.5.**  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \equiv_{\text{sW}} \text{CWO}$ .

*Proof.* By Lemmata 5.6 and 5.7 below.  $\square$

**Lemma 5.6.**  $\text{CWO} \leq_{\text{sW}} \text{UC}_{\mathbb{N}^{\mathbb{N}}}$ .

*Proof.* If  $X, Y \in \mathbf{WO}$ , the conjunction of the three conditions in Definition 5.1 is a  $\Pi_2^0$  formula with  $X, Y$  and  $f$  as free variables. In particular, a name for the  $\Pi_2^0$  set  $\{f\} = \text{CWO}(X, Y)$  is computable from  $X$  and  $Y$ . Then, since  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \equiv_{\text{sW}} \Pi_2^0$ - $\text{UC}_{\mathbb{N}^{\mathbb{N}}}$  by Theorem 3.11 and Proposition 2.3, we can use the second one to obtain  $f$ .  $\square$

**Lemma 5.7.**  $\Sigma_1^1\text{-Sep} \leq_{\text{sW}} \text{CWO}$ .

*Proof.* We follow essentially the proof of Theorem V.6.8 in [41]. The only modification concerns the definition of the well orderings  $U$  and  $V$ , for which the original proof uses the  $\Sigma_1^1$  bounding principle.

So, let  $(S_n, T_n)_{n \in \omega}$  be a double-sequence of trees in  $\text{dom}(\Sigma_1^1\text{-Sep})$ . Without loss of generality we assume that for all  $n \in \mathbb{N}$ ,  $S_n$  and  $T_n$  are non-empty. We can build the corresponding double-sequence of linear orderings  $(X_n, Y_n)_n$  such that, for all  $n$ ,  $X_n = \text{KB}(S_n)$  and  $Y_n = \text{KB}(T_n)$ . Note that, since  $(S_n, T_n)_n \in \text{dom}(\Sigma_1^1\text{-Sep})$ , we have

$$\forall n (\mathbf{WO}(X_n) \vee \mathbf{WO}(Y_n)). \quad (5)$$

Consider  $U = \sum_{n \in \mathbb{N}} (\mathbb{Q} * Y_n) * X_n$ , which by (5) and by Lemma 2.7.1 is a well ordering. We claim that the following holds:

$$\forall X \in \mathbf{LO} \forall n (\neg \mathbf{WO}(X_n) \rightarrow |X * Y_n| < |U|). \quad (6)$$

In fact, let  $X \in \mathbf{LO}$  and  $n$  be such that  $\neg \mathbf{WO}(X_n)$ . Then by (5) we have  $\mathbf{WO}(Y_n)$ , which means that  $X * Y_n$  is also a well ordering. Furthermore, by 3 and 2 of Lemma 2.7, we have  $|X * Y_n| \leq |\mathbb{Q} * Y_n| \leq |(\mathbb{Q} * Y_n) * X_n| < |U|$ .

For all  $n \in \mathbb{N}$ , define  $Z_n = (U + X_n) * Y_n$ . By (6) and by 1 and 2 of Lemma 2.7 we have, for all  $n \in \mathbb{N}$ ,

$$\neg\mathbf{WO}(X_n) \rightarrow |Z_n| < |U|, \quad (7)$$

$$\neg\mathbf{WO}(Y_n) \rightarrow |U| < |Z_n|. \quad (8)$$

Finally, consider  $V = U + \sum_{n \in \mathbb{N}} Z_n$  and define the well orderings

- $Z = \sum_{n \in \mathbb{N}} (Z_n + V \cdot \mathbb{N})$ ,
- $W = \sum_{n \in \mathbb{N}} (V + V \cdot \mathbb{N})$ .

Note that all the well orderings we defined so far, in particular  $Z$  and  $W$ , are computable from the double-sequence  $(X_n, Y_n)_n$ . In the construction of  $V$  we can also use a special mark for its least element. Furthermore, we can code  $Z$  in such a way that, if  $x \in Z_n + V \cdot \mathbb{N}$ , for some  $n \in \mathbb{N}$ , then we are able to compute whether  $x$  belongs to  $Z_n$  or to the first copy of  $V$ , and in the second case, whether  $x$  belongs to the copy of  $U$  contained in  $V$ . Similar assumptions can be made for the construction of  $W$ .

Let now  $f = \text{CWO}(Z, W)$  be the comparing map between  $Z$  and  $W$ . Since  $|Z_n + V \cdot \mathbb{N}| = |V + V \cdot \mathbb{N}|$  for all  $n$ , we have  $|Z| = |W|$  and  $f$  is the isomorphism of  $Z$  onto  $W$ . In particular, for each  $n \in \mathbb{N}$ ,  $f$  induces an isomorphism  $f_n$  of  $Z_n + V \cdot \mathbb{N}$  onto  $V + V \cdot \mathbb{N}$ . Define  $g \in 2^{\mathbb{N}}$  by  $g(n) = 0$  if and only if the image of  $Z_n$  under  $f_n$  is a strict initial segment of  $U$ , i.e.  $|Z_n| < |U|$ . This can be done computably by checking whether  $f_n$  maps the first element of the first copy of  $V$  in  $Z_n + V \cdot \mathbb{N}$  to  $U$  or not. Then, recalling the definition of  $(X_n, Y_n)_n$ , if  $[S_n] \neq \emptyset$  then  $\neg\mathbf{WO}(X_n)$  and, by (7),  $|Z_n| < |U|$  so that  $g(n) = 0$ . Similarly, if  $[T_n] \neq \emptyset$  then, by (8),  $|U| \leq |Z_n|$  so that  $g(n) = 1$ .  $\square$

The Weihrauch degree of weak comparability of well orderings, however, has eluded our classification attempts:

**Question 5.8.** Does  $\text{WCWO} \equiv_W \text{UC}_{\mathbb{N}^{\mathbb{N}}}$ ?

The authors have been informed that Jun Le Goh has obtained a positive answer to our question.

## 6 The one-sided versions of PTT and open determinacy

Both open determinacy and the perfect tree theorem have at its core a disjunction  $A \vee B$  which is **not** to be read constructively. A typical approach to formulate these as computational tasks is to view these as implications  $\neg A \Rightarrow B$  or  $\neg B \Rightarrow A$ . In this section, we explore these variants. In formulating these, we implicitly code strategies in sequential games into Baire space elements.

**Definition 6.1.**  $\text{FindWS}_{\Sigma} : \subseteq \mathcal{O}(\mathbb{N}^{\mathbb{N}}) \Rightarrow \mathbb{N}^{\mathbb{N}}$  ( $\text{FindWS}_{\Pi} : \subseteq \mathcal{O}(\mathbb{N}^{\mathbb{N}}) \Rightarrow \mathbb{N}^{\mathbb{N}}$ ) maps an open game where Player 2 (Player 1) has no winning strategy to a winning strategy for Player 1 (Player 2). Likewise,  $\text{FindWS}_{\Delta}$  maps a clopen game where Player 2 has no winning strategy to a winning strategy for Player 1.

Recall that a tree is perfect if every node has at least two incomparable extensions. In particular, every perfect tree is pruned. The perfect tree theorem states that every tree with uncountably many paths has a perfect subtree and leads to the following two problems: The first problem is given a closed set  $A$  which has no perfect subset (that simply means that  $A$

is countable), and has to show its countability, that is, to enumerate all elements of  $A$ . We consider two variants of this task, depending on what exactly is meant by *listing*. The weak version contains no information about the cardinality, the strong version does. The second problem is more direct: it asks to find a perfect subset of a given tree with uncountably many paths.

**Definition 6.2.**  $w\text{List} : \subseteq \mathcal{A}(\mathbb{N}^{\mathbb{N}}) \Rightarrow (\mathbb{N}^{\mathbb{N}})^{\omega}$  maps a countable set  $A$  to some  $\langle b_0 p_0, b_1 p_1, \dots \rangle$  such that  $A = \{p_i \mid b_i = 1\}$ .  $\text{List} : \subseteq \mathcal{A}(\mathbb{N}^{\mathbb{N}}) \Rightarrow (\mathbb{N}^{\mathbb{N}})^{\omega}$  maps a countable set  $A$  to some  $n \langle p_0, p_1, \dots \rangle$  such that either  $n = 0$ ,  $p_i \neq p_j$  for  $i \neq j$  and  $[T] = \{p_i \mid i \in \mathbb{N}\}$ ; or  $n > 0$ ,  $|[T]| = n - 1$  and  $[T] = \{p_i \mid i < n - 1\}$ .

**Definition 6.3.**  $\text{PTT}_1 : \subseteq \mathbf{Tr} \Rightarrow \mathbf{Tr}$  maps  $T$  such that  $[T]$  is uncountable to some perfect  $T' \subseteq T$ .

We start by reporting a result originating from discussion during the Dagstuhl seminar on Weihrauch reducibility [13], in particular including a contribution by Brattka:

**Proposition 6.4.**  $\text{PTT}_1 \equiv_W C_{\mathbb{N}^{\mathbb{N}}}$ .

*Proof.* For  $C_{\mathbb{N}^{\mathbb{N}}} \leq_W \text{PTT}_1$ , note that from  $A \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  we can compute a tree  $T$  such that  $[T] = A \times \mathbb{N}^{\mathbb{N}}$ . If  $A$  is non-empty, then  $[T]$  is uncountable. Given some perfect subtree  $T'$  of  $T$ , we can compute a path through  $T'$  and hence through  $T$ . By projecting, we obtain a point in  $A$ .

For  $\text{PTT}_1 \leq_W C_{\mathbb{N}^{\mathbb{N}}}$ , call a function  $\lambda : \mathbb{N}^{<\mathbb{N}} \rightarrow \mathbb{N}$  a modulus of perfectness for  $T$ , if  $v \in T$  implies that there are incomparable  $u, w \in [0, \lambda(v)]^{\lambda(v)}$  with  $vu, vw \in T$ . A non-empty tree has a modulus of perfectness iff it is perfect, and given  $T$  the set

$$\{(T', \lambda) \in \mathbf{Tr} \times \mathbb{N}^{(\mathbb{N}^{<\mathbb{N}})} \mid \emptyset \neq T' \subseteq T \wedge \lambda \text{ is a modulus of perfectness for } T'\}$$

is closed, and non-empty for  $[T]$  uncountable by the perfect tree theorem. Taking into account that  $\mathbf{Tr} \times \mathbb{N}^{(\mathbb{N}^{<\mathbb{N}})}$  is computably isomorphic to  $\mathbb{N}^{\mathbb{N}}$ , we can thus apply  $C_{\mathbb{N}^{\mathbb{N}}}$  and project to obtain a perfect subtree of  $T$ .  $\square$

## 6.1 Listing the points in a countable set

We now examine the strength of the contrapositive of the perfect tree theorem  $\text{PTT}_1$ , which is  $\text{List}$  in our setting as explained above.

**Theorem 6.5.**  $w\text{List} \equiv_W \text{List} \equiv_W UC_{\mathbb{N}^{\mathbb{N}}}$ .

The main ingredient of our proof is a variant of the Cantor-Bendixson decomposition, designed in such a way that it can be carried out in a Borel way. This modified version works as the usual one for countable sets, but can differ for uncountable ones<sup>5</sup>.

**Definition 6.6.** A *one-step mCB-certificate* of  $A \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  consists of

- (a) A prefix-independent sequence  $(w_i)_{i \in \mathbb{N}}$  of finite words ordered in a canonical way,
- (b) A sequence of bits  $(b_i)_{i \in \mathbb{N}}$  which are not all 0,

---

<sup>5</sup>Kreisel has shown that computable  $A \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  may have uncomputable Cantor-Bendixson rank [28]. As any total function from  $\mathbb{N}^{\mathbb{N}}$  into the countable ordinals that is effectively Borel is dominated by a computable function (the Spector  $\Sigma_1^1$ -boundedness principle, cf. [37]), this implies that the Cantor-Bendixson decomposition cannot be done in a Borel way.

(c) A sequence of points  $(p_i)_{i \in \mathbb{N}}$   
subject to the following constraints:

1. If  $b_i = 1$ , then  $p_i \in A \cap w_i \mathbb{N}^\mathbb{N}$ .
2. If  $b_i = 0$ , then  $\forall p \in \text{HYP}(A) p \notin A \cap w_i \mathbb{N}^\mathbb{N}$  and  $p_i = 0^\omega$ .
3.  $\forall p, q \in \text{HYP}(A) (p \in A \cap w_i \mathbb{N}^\mathbb{N} \wedge q \in A \cap w_i \mathbb{N}^\mathbb{N} \Rightarrow p = q)$ .
4. If  $w_i \not\preceq w$  for all  $i \in \mathbb{N}$ , then  $\exists p, q \in A \cap w \mathbb{N}^\mathbb{N} p \neq q$ .

For a one-step mCB-certificate for  $A$ , its *residue* is  $A \setminus \bigcup_{i \in \mathbb{N}} w_i \mathbb{N}^\mathbb{N}$ .

**Definition 6.7.** A *global mCB-certificate* for  $A \in \mathcal{A}(\mathbb{N}^\mathbb{N})$  is indexed by some initial  $I \subseteq \mathbb{N}$  (which may be empty). It consists of a sequence  $(c_i)_{i \in I}$  of one-step mCB-certificates such that there exists a linear ordering  $\sqsubseteq \subseteq I \times I$  with minimum 0 (if non-empty), such that  $c_0$  is a one-step mCB-certificate for  $A$ , for each  $n \in I \setminus \{0\}$ ,  $c_n$  is an mCB-certificate for  $\bigcap_{i \sqsubseteq n} A_i$ , where  $A_i$  is the residue of  $c_i$ ; and  $\forall p \in \text{HYP}(A) p \notin A \cap \bigcap_{i \in I} A_i$ .

**Lemma 6.8.** The set of global mCB-certificates of  $A$  is uniformly  $\Sigma^1_1$  in  $A$ .

*Proof.* This is almost immediate from the definition, besides the quantification over HYP. That this is unproblematic follows from Kleene's HYP-quantification theorem [26, 27] (the converse of the Spector-Gandy theorem).  $\square$

**Lemma 6.9.** For non-empty non-perfect  $A \in \mathcal{A}(\mathbb{N}^\mathbb{N})$ ,  $A$  has a one-step mCB-certificate such that its residue is equal to its Cantor-Bendixson derivative. If all points in  $A$  are hyperarithmetical relative to  $A$ , then  $A$  has a unique one-step mCB-certificate.

*Proof.* Let  $(q_j)$  be the finite or infinite list of isolated points in  $A$ , and let  $(u_j)$  be the shortest prefix such that  $A \cap u_j \mathbb{N}^\mathbb{N} = \{q_j\}$ . It follows from Corollary 3.3 applied to  $A \cap u_j \mathbb{N}^\mathbb{N}$  that each  $q_j$  is hyperarithmetical relative to  $A$ . Let  $(v_k)$  be the list of shortest prefixes such that  $A \cap v_k \mathbb{N}^\mathbb{N} = \emptyset$ , excluding those extending some  $u_j$ . Now the sequence  $(w_i)$  is obtained such that  $\{w_i\} = \{u_j\} \cup \{v_k\}$ , subject to the canonical ordering condition. If  $w_i = v_k$ , then  $b_i = 0$  and  $p_i = 0^\omega$ , if  $w_i = u_j$  then  $b_i = 1$  and  $p_i = q_j$ .

It is immediate that the construction satisfies Conditions (1,2,3,4) and that the residue sees exactly the isolated points removed, i.e. is the Cantor-Bendixson derivative of  $A$ . It remains to argue that the mCB-certificate constructed as such is unique if all points in  $A$  are hyperarithmetical relative to  $A$  (this is a classic result, of course). As the choice of  $b_i$  and  $p_i$  was uniquely determined by the sequence  $(w_i)$ , we only need to prove that there is no alternative sequence  $(w'_i)$ . As no  $w_i$  can satisfy the conclusion of Condition (4), we know that for each  $w_i$  there exists some  $w'_{i'}$  with  $w'_{i'} \preceq w_i$ .

Assume that  $w'_{i'} \prec w_i$  for some  $i$ . If  $b_i = 1$ , then  $w_i$  was chosen minimal under the constraint that  $A \cap w_i \mathbb{N}^\mathbb{N}$  is a singleton,  $A \cap w'_{i'}$  contains at least two points, which are both hyperarithmetical. Hence,  $w'_{i'}$  fails Condition (3). If  $b_i = 0$ , then  $w'_{i'} \mathbb{N}^\mathbb{N} \cap A = \emptyset$  contradicts the choice of  $v_k$  as shortest prefix,  $|w'_{i'} \mathbb{N}^\mathbb{N} \cap A| = 1$  contradicts the choice of  $u_j$  as shortest prefix of an isolated point in  $A$ , and  $|w'_{i'} \mathbb{N}^\mathbb{N} \cap A| \geq 2$  again violates Condition (3). Hence we know that all  $(w_i)$  must appear as some  $(w'_{i'})$ .

Assume that there is some  $w$  occurring as a  $w'_{i'}$  but not as a  $w_i$ . As the  $(w'_{i'})$  are prefix-free,  $w$  is not an extension of some  $w_i$ . Hence, Condition (4) for the  $(w_i)$  implies that  $|A \cap w \mathbb{N}^\mathbb{N}| \geq 2$ . But as all points in  $A$  are hyperarithmetical, this shows that neither the conclusion of Condition (2) nor that of Condition (3) can be satisfied for  $w'_{i'} = w$ , and we have obtained the desired contradiction.  $\square$

**Corollary 6.10.** If  $A \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  is countable, then  $A$  has a unique global mCB-certificate, the  $p_i$  for  $b_i = 1$  occurring in some one-step mCB-certificate list all points in  $A$ , and the order type of the implied linear ordering is the Cantor-Bendixson rank of  $A$  plus 1.

*Proof of Theorem 6.5.* That  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \leq_{\text{W}} \text{wList}$  is simple: Any instance of the former is an instance of the latter, and from a list repeating a single element, we can recover that element. For the other direction, we show  $\text{wList} \leq_{\text{W}} \Sigma_1^1\text{-UC}_{\mathbb{N}^{\mathbb{N}}}$  instead and invoke Theorem 3.11. By Lemma 6.8 the set of global mCB-certificates of  $A \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  is computable as a  $\Sigma_1^1$ -set from  $A$ , and by Corollary 6.10 this is a singleton for countable  $A$ . We can distinguish whether the global mCB-certificate uses an empty or non-empty linear order. In the former case, the set is empty, and in the latter case, we can compute a list of all points in  $A$ .

Again,  $\text{wList} \leq_{\text{W}} \text{List}$  is trivial. For the reverse direction, we observe that  $\text{List} \leq_{\text{W}} \text{UC}_{\mathbb{N}^{\mathbb{N}}} \star \text{wList}$ , since  $\text{UC}_{\mathbb{N}^{\mathbb{N}}}$  more than suffices to extract the required additional information from an unstructured list. We then use the preceding result and  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \equiv_{\text{W}} \text{UC}_{\mathbb{N}^{\mathbb{N}}} \star \text{UC}_{\mathbb{N}^{\mathbb{N}}}$  from [5].  $\square$

Regarding the non-uniform aspect, it is known that every countable  $\Pi_1^0$  (indeed  $\Sigma_1^1$ ) set  $A \subseteq \mathbb{N}^{\mathbb{N}}$  consists only of hyperarithmetical elements, cf. Sacks [40, Theorem III.6.2]. Theorem 6.5 concludes that every countable  $\Pi_1^0$  set  $A \subseteq \mathbb{N}^{\mathbb{N}}$  admits a hyperarithmetical enumeration. Combining Proposition 6.4 and Theorem 6.5, we indeed get the following:

**Corollary 6.11.** For any computable tree  $T \subseteq \omega^{<\omega}$ , either  $T$  has a hyperlow perfect subtree or there is a hyperarithmetical enumeration of all infinite paths through  $T$ .

### Listing on Cantor space

We have seen that for subsets of Baire space, it makes no difference whether we intend to list all points of a countable set or all points of a finite set. We briefly explore the corresponding versions for Cantor space. Let  $\text{List}_{2^{\mathbb{N}}, <\omega} : \subseteq \mathcal{A}(2^{\mathbb{N}}) \Rightarrow (2^{\mathbb{N}})^*$  denote the problem to produce a tuple of all elements of a finite closed subset of  $2^{\mathbb{N}}$ . Let  $\text{wList}_{2^{\mathbb{N}}, \leq \omega} : \subseteq \mathcal{A}(2^{\mathbb{N}}) \Rightarrow (2^{\mathbb{N}})^{\omega}$  denote the problem to list all elements of a non-empty countable closed subset of  $2^{\mathbb{N}}$ . Note that  $\text{List}_{2^{\mathbb{N}}, <\omega}$  is not a restriction of  $\text{wList}_{2^{\mathbb{N}}, \leq \omega}$ , since finite tuples and lists with finite range have distinct properties. We will in fact show in Corollary 6.16 that these two multivalued functions are incomparable with respect to Weihrauch reducibility.

**Proposition 6.12.**  $\text{List}_{2^{\mathbb{N}}, <\omega} \equiv_{\text{W}} \Pi_2^0\text{-C}_\mathbb{N}$ .

*Proof.* To see that  $\text{List}_{2^{\mathbb{N}}, <\omega} \leq_{\text{W}} \Pi_2^0\text{-C}_\mathbb{N}$ , note that we can guess a finite partition of  $2^{\mathbb{N}}$  into clopens  $A_0, \dots, A_n$  such that  $|A \cap A_i| = 1$  for input  $A$  and any  $i$ . Verifying a correct partition is  $\Pi_2^0$  (because  $A \cap A_i \neq \emptyset$  and  $|A \cap A_i| \leq 1$  are respectively a  $\Pi_2^0$  and a  $\Sigma_1^0$  condition), and given a correct partition, we can compute the listing since  $\text{UC}_{2^{\mathbb{N}}}$  is computable.

For the other direction, note that we can view  $\Pi_2^0\text{-C}_\mathbb{N}$  as the following task: Given  $(p_0, p_1, \dots) \in (2^{\mathbb{N}})^{\omega}$  with the promise that if  $|\{j \mid p_i(j) = 1\}| = \infty$  then  $|\{j \mid p_{i+1}(j) = 1\}| = \infty$ , and that there exists some  $i$  with  $|\{j \mid p_i(j) = 1\}| = \infty$ , find such an  $i$  (for details, see [9]). We now construct  $A \in 2^{\mathbb{N}}$  as follows: For each  $i$ , keep track of an auxiliary variable  $k_i$ , which is initially 0. Start enumerating all  $0^{(i,k)}1$  into the complement of  $A$  except the  $0^{(i,k_i)}1$ . Also enumerate all  $0^l 1^s 0$ . Whenever we read another 1 in  $p_i$ , we do enumerate  $0^{(i,k_i)}1$ , and set the new  $k_i$  to be the least  $k$  such that  $0^{(i,k)}1$  has not been enumerated yet.

Whenever  $|\{j \mid p_i(j) = 1\}| < \infty$  for some  $i$ , then  $k_i$  will eventually remain constant. The resulting set  $A$  will be of the form  $\{0^\omega\} \cup \{0^{\langle i, k_i \rangle} 1^\omega \mid i \in I\}$  where  $I$  is the finite set of non-solutions. Having a finite listing of  $A$  lets us easily pick some solution.  $\square$

As a corollary one can see that every finite  $\Pi_1^0$  subset of  $2^\mathbb{N}$  admits a computable listing uniformly in  $\mathbf{0}''$ , and the complexity  $\mathbf{0}''$  is optimal: If a function  $f$  sends an index of a  $\Pi_1^0$  set  $P \subseteq 2^\mathbb{N}$  to an index of a computable listing of elements of  $P$  whenever  $P$  is finite, then  $f$  must compute  $\mathbf{0}''$ .

**Proposition 6.13.**  $wList_{2^\mathbb{N}, \leq \omega} \equiv_W \widehat{wList}_{2^\mathbb{N}, \leq \omega} \leq_W UC_{\mathbb{N}^\mathbb{N}} \equiv_W \Pi_2^0 \text{-} C_{\mathbb{N}} * wList_{2^\mathbb{N}, \leq \omega}$ .

*Proof.* To note that  $wList_{2^\mathbb{N}, \leq \omega}$  is parallelizable, observe that we can effectively join countably many trees along a comb, and the set of paths of the result is essentially the disjoint union of the original paths. The second reduction follows from the obvious embedding of  $2^\mathbb{N}$  into  $\mathbb{N}^\mathbb{N}$  as a closed set and Theorem 6.5. For the third reduction, note that we can embed  $\mathbb{N}^\mathbb{N}$  as a  $\Pi_2^0$ -subspace  $B$  into  $2^\mathbb{N}$  such that  $2^\mathbb{N} \setminus B$  is countable. Given some singleton  $A \in \mathcal{A}(\mathbb{N}^\mathbb{N})$ , we can compute some countable  $\bar{A} \in \mathcal{A}(2^\mathbb{N})$  such that  $\bar{A} \cap B$  is the image of  $A$  under that embedding. If we have a list of all points in  $\bar{A}$ , we can then use  $\Pi_2^0 \text{-} C_{\mathbb{N}}$  to pick the one in  $B$ . That the third reduction is an equivalence follows from the second, the observation that  $\Pi_2^0 \text{-} C_{\mathbb{N}} \leq_W UC_{\mathbb{N}^\mathbb{N}}$  and  $UC_{\mathbb{N}^\mathbb{N}} * UC_{\mathbb{N}^\mathbb{N}} \equiv_W UC_{\mathbb{N}^\mathbb{N}}$  (cf. [5]).  $\square$

**Proposition 6.14.**  $\lim \leq_W wList_{2^\mathbb{N}, \leq \omega}$ .

*Proof.* Consider the map  $\text{id} : \mathcal{A}(\mathbb{N}) \rightarrow \mathcal{O}(\mathbb{N})$  translating an enumeration of a complement of a set to an enumeration of the set. Studied under the name EC in [42], it is known to be equivalent to  $\lim$ . Now from  $A \in \mathcal{A}(\mathbb{N})$  we can compute  $\{0^\omega\} \cup \{0^n 1^\omega \mid n \in A\} \in \mathcal{A}(2^\mathbb{N})$ . From any list of the elements of the latter set, we can then compute  $A \in \mathcal{O}(\mathbb{N})$ .  $\square$

**Proposition 6.15.** The following are equivalent for single-valued  $f : \mathbf{X} \rightarrow \mathbb{N}^\mathbb{N}$ :

1.  $f \leq_W \lim$ .
2.  $f \leq_W wList_{2^\mathbb{N}, \leq \omega}$ .

*Proof.* Proposition 6.14 entails that 1. implies 2.

To see that 2. implies 1., consider some single-valued  $f : \subseteq \mathbb{N}^\mathbb{N} \rightarrow \mathbb{N}^\mathbb{N}$  with  $f \leq_W wList_{2^\mathbb{N}, \leq \omega}$ . So from any  $p \in \text{dom}(f)$ , we can compute some countable  $A_p \in \mathcal{A}(2^\mathbb{N})$ , and from any enumeration of the points in  $A_p$  together with  $p$  we can compute  $f(p)$  via some computable  $K$ . We will argue that having access to a pruned tree  $T$  with  $[T] = A_p$  suffices to compute  $f(p)$ , and note that pruning a binary tree is equivalent to  $\lim$  (see e.g. [33]). Let us assume that there are prefix  $w_0, \dots, w_n$  in the pruned tree such that  $K$  upon reading  $p$  and  $w_0, \dots, w_n$  outputs some prefix  $w$ . Then there is some enumeration  $q_0, q_1, \dots$  of points in  $A_p$  such that  $w_0, \dots, w_n$  are prefixes of  $q_0, \dots, q_n$ , hence  $w$  is a prefix of  $f(p)$ . Conversely, for any fixed enumeration  $q_0, q_1, \dots$  of points in  $A_p$  and desired prefix length  $m$  of  $f(p)$  there is some  $k \in \mathbb{N}$  such that  $K$  outputs  $f(p)_{\leq m}$  after having read no more than the  $k$ -length prefixes of  $q_i$  for  $i \leq k$ . Moreover, each  $(q_i)_{\leq k}$  occurs in the pruned tree  $T$ . Thus, having access to  $T$  lets us compute longer and longer prefixes of  $f(p)$ , and since  $f$  is single-valued, this suffices to compute  $f(p)$ .  $\square$

In particular,  $A \subseteq \mathbb{N}$  is computable from all listings of some countable  $\Pi_1^0$  set  $P \subseteq 2^\mathbb{N}$  iff  $A$  is  $\mathbf{0}'$ -computable. On the other hand, there is no computable ordinal  $\alpha$  such that  $\mathbf{0}^{(\alpha)}$  computes a listing of any countable  $\Pi_1^0$  subset of  $2^\mathbb{N}$ .

**Corollary 6.16.**  $\text{List}_{2^\mathbb{N}, <\omega} \not\leq_w \text{wList}_{2^\mathbb{N}, \leq \omega}$  and  $\text{wList}_{2^\mathbb{N}, \leq \omega} \not\leq_w \text{List}_{2^\mathbb{N}, <\omega}$ .

*Proof.* For the first claim, it is known that  $\mathbf{\Pi}_2^0\text{-C}_\mathbb{N} \equiv_w \mathbf{\Pi}_2^0\text{-UC}_\mathbb{N}$  [9]. (Sketch: Take  $(p_i)_{i \in \mathbb{N}}$  as in Proposition 6.12, and then put  $\hat{p}_{i,s}(n) = 1$  iff  $p_i(n) = 1$  and  $p_j(t) = 0$  for all  $j < i$  and  $s \leq t < n$ . It is easy to see that there is a unique  $i, s$  such that  $|\{n \mid \hat{p}_{i,s}(n) = 1\}| = \infty$ , and then  $|\{n \mid p_i(n) = 1\}| = \infty$ .) Then observe that  $\mathbf{\Pi}_2^0\text{-UC}_\mathbb{N}$  is single-valued, and that  $\lim$  is  $\Sigma_2^0$ -computable while  $\mathbf{\Pi}_2^0\text{-C}_\mathbb{N}$  is not.

The second claim follows from the observation that any solution of a computable instance of  $\mathbf{\Pi}_2^0\text{-C}_\mathbb{N}$  must be computable while  $\lim$  is not.  $\square$

**Corollary 6.17.**  $\text{wList}_{2^\mathbb{N}, \leq \omega} <_w \text{wList}_{2^\mathbb{N}, \leq \omega} * \text{wList}_{2^\mathbb{N}, \leq \omega} * \text{wList}_{2^\mathbb{N}, \leq \omega} \equiv_w \text{UC}_{\mathbb{N}^\mathbb{N}}$ .

*Proof.* In Proposition 6.14 we have shown that  $\lim \leq_w \text{List}_{2^\mathbb{N}, \leq \omega}$ , which implies  $\mathbf{\Pi}_2^0\text{-C}_\mathbb{N} \leq_w \lim * \lim \leq_w \text{wList}_{2^\mathbb{N}, \leq \omega} * \text{wList}_{2^\mathbb{N}, \leq \omega}$ ; hence the assertion follows from Proposition 6.13 and  $\text{UC}_{\mathbb{N}^\mathbb{N}} * \text{UC}_{\mathbb{N}^\mathbb{N}} \equiv_w \text{UC}_{\mathbb{N}^\mathbb{N}}$ . The strictness follows from Proposition 6.15 since  $\text{UC}_{\mathbb{N}^\mathbb{N}}$  is single-valued and  $\text{UC}_{\mathbb{N}^\mathbb{N}} \not\leq_w \lim$ .  $\square$

**Question 6.18.** Does  $\text{wList}_{2^\mathbb{N}, \leq \omega} * \text{wList}_{2^\mathbb{N}, \leq \omega} \equiv_w \text{UC}_{\mathbb{N}^\mathbb{N}}$  hold?

The feature that  $\text{List}_{2^\mathbb{N}, \leq \omega}$  is not closed under composition itself, but that the hierarchy of more and more compositions stabilizes at a finite level, seems surprising for a *natural* degree. A similar observation was made before regarding the degree of finding Nash equilibria in bimatrix games [25].

## 6.2 Finding winning strategies

We now move on to the complexity of finding winning strategies in open Gale-Stewart games. On the one hand, the difficulty of finding a winning strategy for a closed player is the same as the closed choice on Baire space.

**Proposition 6.19.**  $\text{FindWS}_{\mathbf{\Pi}} \equiv_w \text{C}_{\mathbb{N}^\mathbb{N}}$ .

*Proof.* For  $\text{C}_{\mathbb{N}^\mathbb{N}} \leq_w \text{FindWS}_{\mathbf{\Pi}}$ , note that we can turn any  $A \in \mathcal{A}(\mathbb{N}^\mathbb{N})$  into a  $\Sigma_1^0$  game where Player 1's moves do not matter, and Player 2 wins iff his moves form a point  $p \in A$ .

For  $\text{FindWS}_{\mathbf{\Pi}} \leq_w \text{C}_{\mathbb{N}^\mathbb{N}}$ , note that given a Player 2 strategy  $\tau$  and the  $\Sigma_1^0$  winning condition  $W \subseteq \mathbb{N}^\mathbb{N}$  we can compute a tree  $T_{W,\tau}$  describing the options available to Player 1: Essentially, the strategies  $\sigma$  winning against  $\tau$  correspond to finite paths in  $T_{W,\tau}$  ending in a leaf, whereas strategies  $\sigma'$  losing against  $\tau$  correspond to infinite paths through  $T_{W,\tau}$ . Thus,  $\tau$  is a winning strategy for Player 2 iff  $T_{W,\tau}$  is a pruned tree, i.e. a tree without any leaves. Let  $\lambda : \mathbb{N}^* \rightarrow \mathbb{N}$  be a witness of prunedness of  $T$  iff  $\forall v \in T \ v\lambda(v) \in T$ . If Player 2 has a winning strategy for the game  $W$ , then the set

$$\{(\tau, \lambda) \mid \lambda \text{ is a witness of prunedness for } T_{W,\tau}\}$$

is a non-empty closed set computable from  $W$ , and projecting a member of it yields a winning strategy for Player 2.  $\square$

On the other hand, the difficulty of finding a winning strategy for a open/clopen player is the same as the unique choice on Baire space. In the case of clopen games, we even get full determinacy defined as follows:

**Definition 6.20.**  $\text{Det}_\Delta : \Delta_1^0(\mathbb{N}^\mathbb{N}) \rightrightarrows \mathbb{N}^\mathbb{N} \times \mathbb{N}^\mathbb{N}$  maps a clopen game  $W$  to a pair of strategies  $\sigma, \tau$  such that either  $\sigma$  is winning for Player 1 or  $\tau$  is winning for Player 2 (i.e. a Nash equilibrium).

**Theorem 6.21.**  $\text{FindWS}_\Delta \equiv_W \text{Det}_\Delta \equiv_W \text{FindWS}_\Sigma \equiv_W \text{UC}_{\mathbb{N}^\mathbb{N}}$ .

We will prove Theorem 6.21 using the next Lemmata.

**Lemma 6.22.**  $\text{FindWS}_\Sigma \leq_W \Sigma_1^1\text{-UC}_{\mathbb{N}^\mathbb{N}}$ .

*Proof.* Let  $T$  be a tree describing the complement of some open set, the payoff for Player 1. Fix some strategy  $\sigma$  of Player 1. We understand this to prescribe the action even at positions made impossible by  $\sigma$  itself. For any  $v \in \mathbb{N}^*$  where Player 1 moves, consider the trees  $T_i^v$  describing the options available to Player 2 if the game starts at  $v$ , Player 1 plays  $i$  and otherwise follows  $\sigma$ .  $\sigma$  is a winning strategy iff for any  $v$  compatible with  $\sigma$  we find that  $T_{\sigma(v)}^v$  is well-founded. Only  $\Sigma_1^1\text{-UC}_{\mathbb{N}^\mathbb{N}}$  is available here while a lot of strategies may exist. We overcome this difficulty by considering the optimal strategy, that is, the one that minimizes the rank of  $T_{\sigma(v)}^v$ .

Let  $v$  be a position where Player 1 moves. A certificate of optimality for  $\sigma$  at  $v$  describes maps preserving  $\sqsubset$  from  $T_{\sigma(v)}^v$  to  $T_i^v \setminus \{\lambda\}$  (here  $\lambda$  denotes the empty sequence) for every  $i < \sigma(v)$ , and maps preserving  $\sqsubset$  from  $T_{\sigma(v)}^v$  to  $T_j^v$  for every  $j > \sigma(v)$ . The set of strategies  $\sigma$  and corresponding certificates of optimality for all positions is a closed set computable from the game.

If we fix partial strategies of all proper extensions of  $v$  such that Player 1 can win from  $v$ , then there is a unique action of Player 1 at  $v$  such that extending the strategy to  $v$  admits a certificate of optimality. It follows that if Player 1 has a winning strategy, then there is a unique strategy admitting a certificate of optimality at all compatible positions; and this strategy is winning. We can compute this using  $\Sigma_1^1\text{-UC}_{\mathbb{N}^\mathbb{N}}$ .  $\square$

**Corollary 6.23.**  $\text{FindWS}_\Sigma \leq_W \text{UC}_{\mathbb{N}^\mathbb{N}}$ .

*Proof.* By Lemma 6.22 and Theorem 3.11.  $\square$

**Lemma 6.24.**  $\text{Det}_\Delta \leq_W \text{FindWS}_\Delta$ .

*Proof.* Given a  $\Delta_1^0$ -game  $G$ , we can compute the derived  $\Delta_1^0$ -game  $G'$  where the first player can decide whether to play  $G$  as Player 1, or as Player 2, and then proceed a play of a chosen side. Thus, Player 1 can definitely win  $G'$ , and a winning strategy of Player 1 in  $G'$  tells us who wins  $G$  and how.  $\square$

**Lemma 6.25.**  $\widehat{\text{FindWS}}_\Delta \leq_W \text{FindWS}_\Delta$ .

*Proof.* Given a sequence  $G_0, G_1, \dots$  of  $\Delta_1^0$ -games all won by Player 1, we combine them into a single  $\Delta_1^0$  game where Player 2 first chooses  $n$ , and then the players play  $G_n$ . Player 1 wins the combined game, and any winning strategy in that game yields in the obvious way winning strategies for every  $G_i$ .  $\square$

Let  $\mathbb{S}_B$  denote the space of Borel-truth values (cf. [21, 37]). Roughly speaking, if  $p$  is a Borel code of a Borel subset  $A$  of the singleton space  $\{\bullet\}$ , then we think of  $p$  as a name of  $\top$  ( $\perp$ , resp.) iff  $A \neq \emptyset$  ( $A = \emptyset$ , resp.); if  $p$  is not a Borel code,  $p$  is not in the domain of the representation.

**Lemma 6.26.**  $(\text{id} : \mathbb{S}_{\mathcal{B}} \rightarrow \mathbf{2}) \leq_{\text{W}} \text{Det}_{\Delta}$ .

*Proof.* A Borel code can be viewed as a well-founded tree whose even-levels (odd-levels, resp.) consist of  $\exists$ -vertices ( $\forall$ -vertices, resp.) and leaves are labeled by either  $\top$  or  $\perp$  (corresponding to either  $\{\bullet\}$  or  $\emptyset$ ) [21, 37]. We can turn a  $\mathbb{S}_{\mathcal{B}}$ -name into a  $\Delta_1^0$ -game by letting Player 1 control the  $\exists$ -vertices, Player 2 the  $\forall$ -vertices, make the  $\top$ -leaves winning for Player 1 and the  $\perp$ -leaves losing. Then Player 1 has a winning strategy iff the value of the root is  $\top$ . Given a Nash equilibrium  $(\sigma, \tau)$  we can compute the leaf reached by the induced play, and find it to be equal to the truth value of the root.  $\square$

*Proof of Theorem 6.21.* As shown in [37],  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \leq_{\text{W}} (\text{id} : \widehat{\mathbb{S}_{\mathcal{B}}} \rightarrow \mathbf{2})$ . By Lemma 6.26, the latter is reducible to  $\widehat{\text{Det}_{\Delta}}$ . This is reducible to  $\widehat{\text{FindWS}_{\Delta}}$  by Lemma 6.24, which in turn reduces to  $\text{FindWS}_{\Delta}$  by Lemma 6.25.  $\text{FindWS}_{\Delta} \leq_{\text{W}} \text{Det}_{\Delta}$  is trivial, and so is  $\text{FindWS}_{\Delta} \leq_{\text{W}} \text{FindWS}_{\Sigma}$ .  $\text{FindWS}_{\Sigma} \leq_{\text{W}} \text{UC}_{\mathbb{N}^{\mathbb{N}}}$  follows by Corollary 6.23.  $\square$

As in the case of the perfect tree theorem (Corollary 6.11), the results in this section can be viewed as a refinement of the following known result [2]:

**Corollary 6.27.** For any open game, either the open player has a hyperarithmetical winning strategy or the closed player has a hyperlow winning strategy.

## 7 The two-sided versions of PTT and open determinacy

Rather than demanding a promise about the case of the theorem we are in, we could alternatively consider the task completely uniformly. As distinguishing the two cases is a  $\Pi_1^1$ -complete question (cf. the well-known equation  $\partial\Sigma_1^0 = \Pi_1^1$ ), the fully uniform task should **not** include an answer to the which case we are in. A priori, since we considered two versions of listing, we also have the two corresponding version of the two-sided perfect tree theorem. We are left with the following formulations:

**Definition 7.1.**  $\text{wPTT}_2 : \text{Tr} \rightrightarrows \text{Tr} \times \mathbb{N}^{\mathbb{N}}$  has  $(T', \langle b_0 p_0, b_1 p_1, b_2 p_2, \dots \rangle) \in \text{wPTT}_2(T)$  iff one of the following holds:

- $T'$  is a perfect subtree of  $T$ ;
- $[T] = \{p_i \mid b_i \neq 0\}$

**Definition 7.2.**  $\text{PTT}_2 : \text{Tr} \rightrightarrows \text{Tr} \times \mathbb{N}^{\mathbb{N}}$  has  $(T', n \langle p_0, p_1, p_2, \dots \rangle) \in \text{PTT}_2(T)$  iff one of the following holds:

- $T'$  is a perfect subtree of  $T$ ;
- $n = 0$ ,  $p_i \neq p_j$  for  $i \neq j$  and  $[T] = \{p_i \mid i \in \mathbb{N}\}$ ;
- $n > 0$ ,  $|[T]| = n - 1$  and  $[T] = \{p_i \mid i < n - 1\}$ .

**Definition 7.3.**  $\text{Det}_{\Sigma} : \mathcal{O}(\mathbb{N}^{\mathbb{N}}) \rightrightarrows \mathbb{N}^{\mathbb{N}} \times \mathbb{N}^{\mathbb{N}}$  maps an open game  $W$  to a pair of strategies  $\sigma, \tau$  such that either  $\sigma$  is winning for Player 1 or  $\tau$  is winning for Player 2.

These variants are strictly harder than the non-uniform ones (which are Weihrauch reducible to  $\mathsf{C}_{\mathbb{N}^{\mathbb{N}}}$  by the results of Section 6). To see that, let  $\chi_{\Pi_1^1} : \mathbb{N}^{\mathbb{N}} \rightarrow \mathbf{2}$  be the characteristic function of a  $\Pi_1^1$ -complete set. Since the single-valued functions between computable Polish spaces which are Weihrauch reducible to  $\mathsf{C}_{\mathbb{N}^{\mathbb{N}}}$  are exactly those that are effectively Borel measurable ([5, Theorem 7.7]), and  $\chi_{\Pi_1^1}$  is not such, we have  $\chi_{\Pi_1^1} \not\leq_{\text{W}} \mathsf{C}_{\mathbb{N}^{\mathbb{N}}}$ .

**Observation 7.4.**  $\chi_{\Pi_1^1} \leq_w \text{LPO}' * \text{wPTT}_2$  and  $\chi_{\Pi_1^1} \leq_w \text{LPO} * \text{Det}_\Sigma$ .

*Proof.* Deciding whether  $[T]$  is uncountable and who wins a  $\Sigma_1^0$ -game are  $\Pi_1^1/\Sigma_1^1$ -complete decision problems. Given trees  $T'$  and  $T$ , we can use  $\text{LPO}'$  to decide whether or not  $T'$  is a perfect subtree of  $T$ . Given a Nash equilibrium  $(\sigma, \tau)$  of a  $\Sigma_1^0$ -game, we can compute the induced play and then use  $\text{LPO}$  to decide who wins that play – and this is the same player that has a winning strategy in the game.  $\square$

**Corollary 7.5.**  $C_{\mathbb{N}^\mathbb{N}} <_w \text{wPTT}_2 \leq_w \text{PTT}_2$  and  $C_{\mathbb{N}^\mathbb{N}} <_w \text{Det}_\Sigma$ .

*Proof.* Using the fact that  $C_{\mathbb{N}^\mathbb{N}}$  is closed under composition [5, Corollary 7.6] we have  $\chi_{\Pi_1^1} \not\leq_w C_{\mathbb{N}^\mathbb{N}} \equiv_w \text{LPO} * C_{\mathbb{N}^\mathbb{N}} \equiv_w \text{LPO}' * C_{\mathbb{N}^\mathbb{N}}$ .  $\square$

In particular, we find that  $\text{FindWS}_\Sigma <_w \text{Det}_\Sigma$  and  $\text{FindWS}_\Pi <_w \text{Det}_\Sigma$ . Thus, knowing who wins a  $\Sigma_1^0$ -game makes it strictly easier to find a Nash equilibrium. This is in contrast to  $\Delta_1^0$ -games (as seen in Theorem 6.21), as well as to games on Cantor space with winning sets in the difference hierarchy over  $\Sigma_1^0$  (cf. [29]). Knowing who wins the game allows for constructions such as the one used in Lemma 6.25 to conclude that finding a winning strategy is parallelizable (i.e.  $\widehat{\text{FindWS}}_\Sigma \equiv_w \text{FindWS}_\Sigma$  and  $\widehat{\text{FindWS}}_\Pi \equiv_w \text{FindWS}_\Pi$ ). We will see in Corollary 7.13 below that this is not just an obstacle for the proof strategy, but that the result differs for  $\text{Det}_\Sigma$ .

### If then else

As we have seen, many theorems equivalent to  $\text{ATR}_0$  are described as *dichotomy*-type theorems: Exactly one of  $A$  or  $B$  holds. Thus, it is natural to consider the following if-then-else problem for a given dichotomy  $A$  xor  $B$ : Provide two descriptions  $(\alpha, \beta)$  trying to verify  $A$  and  $B$  simultaneously. If  $A$  is true, then  $\alpha$  is a correct proof validating  $A$ ; or else  $\beta$  is a correct proof of  $B$ , where we do not need to know which one is correct. We formalize this idea as follows.

A space of truth values is just a represented space  $\mathbb{B}$  with underlying set  $\{\top, \perp\}$ .

**Definition 7.6.** Let  $\mathbb{B}$  be a space of truth values. For  $f : \subseteq \mathbf{X} \rightrightarrows \mathbf{Y}$  and  $g : \subseteq \mathbf{A} \rightrightarrows \mathbf{B}$ , we define

$$[\text{if } \mathbb{B} \text{ then } f \text{ else } g] : \subseteq \mathbb{B} \times \mathbf{X} \times \mathbf{A} \rightrightarrows \mathbf{Y} \times \mathbf{B}$$

via  $(b, x_0, x_1) \in \text{dom}([\text{if } \mathbb{B} \text{ then } f \text{ else } g])$  iff  $b = \top$  and  $x_0 \in \text{dom}(f)$  or  $b = \perp$  and  $x_1 \in \text{dom}(g)$ , and  $(y_0, y_1) \in [\text{if } \mathbb{B} \text{ then } f \text{ else } g](b, x_0, x_1)$  iff  $b = \top$  and  $y_0 \in f(x_0)$  or  $b = \perp$  and  $y_1 \in g(x_1)$ .

Note that the degree of  $[\text{if } \mathbb{B} \text{ then } f \text{ else } g]$  depends on the precise choice of spaces for domain and codomains involved, beyond what matters for where  $f$  and  $g$  are actually defined and are taking their range. In particular,  $[\text{if } \mathbb{B} \text{ then } f \text{ else } g]$  is not an operation on Weihrauch degrees<sup>6</sup>.

---

<sup>6</sup>Let  $\mathbf{X}$  be the represented space of the non-computable elements of  $\mathbb{N}^\mathbb{N}$ , and  $f : \subseteq \mathbb{N}^\mathbb{N} \rightarrow \mathbb{N}^\mathbb{N}$  the restriction of  $\text{id}_{\mathbb{N}^\mathbb{N}}$  to the non-computable elements ( $\text{id}_{\mathbf{X}}$  and  $f$  are the same function, but defined on different spaces); then  $\text{id}_{\mathbf{X}} \equiv_w f$ , yet  $[\text{if } \mathbb{S} \text{ then } f \text{ else } \text{id}_{\mathbb{N}^\mathbb{N}}] \not\leq_w [\text{if } \mathbb{S} \text{ then } \text{id}_{\mathbf{X}} \text{ else } \text{id}_{\mathbb{N}^\mathbb{N}}]$  because the former has computable inputs while the latter does not.

### The upper bound

Let  $\mathbb{S}_{\Sigma_1^1}$  be the space of truth values where  $p$  is a name for  $\top$  iff  $p$  codes an ill-founded tree, and a name for  $\perp$  iff it codes a well-founded tree.

In the proofs of Propositions 6.4 and 6.19, we constructed closed sets containing information over the perfect subtrees or the winning strategies of Player 2 respectively. In particular, by testing whether these are empty or not, we can decide in which case we are, and obtain the answer in  $\mathbb{S}_{\Sigma_1^1}$ . Thus, by combining Proposition 6.4 and Theorem 6.5, respectively Proposition 6.19 and Theorem 6.21, we obtain the following:

**Corollary 7.7.**  $\text{PTT}_2 \leq_W [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$ .

**Corollary 7.8.**  $\text{Det}_\Sigma \leq_W [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$ .

As  $UC_{\mathbb{N}^\mathbb{N}} \leq_W C_{\mathbb{N}^\mathbb{N}}$ , it follows that  $[\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}] \leq_W C_{\mathbb{N}^\mathbb{N}} * \chi_{\Pi_1^1}$ . In particular, the difference between  $[\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$  and  $C_{\mathbb{N}^\mathbb{N}}$  disappears if we move from Weihrauch reducibility to computable reducibility. It follows immediately that Gandy's basis theorem applies to  $\text{Det}_\Sigma$ : Every  $\Sigma_1^0$ -game has a Nash equilibrium that is hyperlow relative to the game.

### Idempotency

We can show a kind of absorption result for the if-then-else construction. Recall that  $\text{NHA}$  asks for an output that is not hyperarithmetical relative to the input.

**Proposition 7.9.** Let  $g$  have a hyperarithmetical point  $\rho$  in its codomain. If we have  $f \times \text{NHA} \leq_W [\text{if } \mathbb{B} \text{ then } g \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$ , then  $f \leq_W g$ .

*Proof.* Any  $x \in \text{dom}(f)$  is provided in the form of some name  $p_x$ , which is a valid input to  $\text{NHA}$ . If some  $(x, p_x) \in \text{dom}(f \times \text{NHA})$  were mapped to some  $(\perp, a, A)$  via the reduction, then  $A = \{q\}$  where  $q$  is hyperarithmetical in  $p_x$ . Then  $(\rho, q)$  is a valid output of  $[\text{if } \mathbb{B} \text{ then } g \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$ , but we cannot compute a solution to  $\text{NHA}(p_x)$  from  $(\rho, q)$ .

Thus, every  $(x, p_x)$  gets mapped to  $(\top, a_x, A)$  such that from  $b \in g(a_x)$  we can compute  $y \in f(x)$  (since  $(b, z)$  for any  $z$ , say  $(b, \emptyset)$ , is a solution to the instance  $(\top, a_x, A)$ ). This provides the claimed reduction  $f \leq_W g$ .  $\square$

By Corollaries 7.5, 7.8 and 7.7, and Proposition 7.9 we get the following:

**Corollary 7.10.**  $w\text{PTT}_2 \times \text{NHA} \not\leq_W [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$ .

**Corollary 7.11.**  $\text{Det}_\Sigma \times \text{NHA} \not\leq_W [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$ .

Using the corollaries above in conjunction with Corollary 3.6, we obtain:

**Corollary 7.12.**  $w\text{PTT}_2 \times C_{\mathbb{N}^\mathbb{N}} \not\leq_W \text{PTT}_2$  and hence  $w\text{PTT}_2 \times w\text{PTT}_2 \not\leq_W \text{PTT}_2$ .

**Corollary 7.13.**  $\text{Det}_\Sigma \times C_{\mathbb{N}^\mathbb{N}} \not\leq_W \text{Det}_\Sigma$  and hence  $\text{Det}_\Sigma \times \text{Det}_\Sigma \not\leq_W \text{Det}_\Sigma$ .

### Products with $UC_{\mathbb{N}^\mathbb{N}}$

While we just saw that  $\text{Det}_\Sigma$ ,  $\text{PTT}_2$  and  $[\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$  are not closed under products with  $C_{\mathbb{N}^\mathbb{N}}$ , the situation for products with  $UC_{\mathbb{N}^\mathbb{N}}$  is different:

**Proposition 7.14.**  $UC_{\mathbb{N}^\mathbb{N}} \times [\text{if } \mathbb{B} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}] \equiv_W [\text{if } \mathbb{B} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } UC_{\mathbb{N}^\mathbb{N}}]$  for any space of truth values  $\mathbb{B}$ .

*Proof.* Let  $\{a\}$ ,  $b \in \mathbb{B}$ ,  $A$ ,  $B$  be the input to  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \times [\text{if } \mathbb{B} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}]$ . We can use  $[\text{if } \mathbb{B} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}]$  on  $b$ ,  $\{a\} \times A$  and  $\{a\} \times B$ , as  $\{a\} \times A$  is non-empty iff  $A$  is, and  $\{a\} \times B$  is a singleton iff  $B$  is. We will receive as output  $(\langle p, x \rangle, \langle q, y \rangle)$  such that  $\langle x, y \rangle$  is a valid output to  $[\text{if } \mathbb{B} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}] (b, A, B)$ , and at least one of  $p$  and  $q$  is  $a$ . Let us write  $p_{\leq n}$  for the prefix of  $p$  of length  $n + 1$ . We have that, if  $p_{\leq n} = q_{\leq n}$ , then  $p_{\leq n} = a_{\leq n}$ , and if  $p_{\leq n} \neq q_{\leq n}$ , then either  $p \notin \{a\}$  or  $q \notin \{a\}$ , hence we can compute  $a$  from  $p$ ,  $q$  and  $\{a\}$ .  $\square$

**Proposition 7.15.**  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \times \text{PTT}_2 \equiv_w \text{PTT}_2$ .

*Proof.* Let  $(\{a\}, T)$  be the input to  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \times \text{PTT}_2$ . From this input we can build a tree  $T_0$  such that  $[T_0] = \{a\} \times (\{0^\omega\} \cup 1[T])$  (notice that  $|[T_0]| = |[T]| + 1$ ).  $\text{PTT}_2(T_0)$  yields a tree  $T'$  and a sequence  $n(\langle q_0, t_0 p_0 \rangle, \langle q_1, t_1 p_1 \rangle, \dots)$ .

We first explain how to compute the sequence part of  $\text{PTT}_2(T)$ . If  $n = 1$ , or  $n = 0$  and more than one  $t_i$  is 0, or  $n > 1$  and more than one  $t_i$  for  $i < n - 1$  is 0, then the sequence is not listing  $[T_0]$  (because  $[T_0] \neq \emptyset$  and  $(a, 0^\omega)$  is the only member of  $[T_0]$  whose second component starts with 0), which implies that  $[T_0]$ , and hence  $[T]$ , was uncountable. In this case, we can just output some arbitrary sequence. Otherwise let  $p'_i$  be the sequence consisting of the odd digits of  $p_i$ . If  $n = 0$ , we output  $0(p'_{i_0}, p'_{i_1}, \dots)$  where the  $i_k$  are the (all but one) indices such that  $t_i \neq 0$  (in this way, if  $(\langle q_0, t_0 p_0 \rangle, \langle q_1, t_1 p_1 \rangle, \dots)$  lists injectively  $[T_0]$ , our output lists injectively  $[T]$ ). To achieve the same result when  $n > 1$  we output  $(n - 1)p'_{i_0}, p'_{i_1}, \dots)$  where we are omitting the (at most one)  $i < n - 1$  such that  $t_i = 0$ .

To compute the tree part of  $\text{PTT}_2(T)$ , starting from  $T'$  we obtain a tree  $T''$  as follows: On the first three levels (corresponding to the first two digits of  $a$  and the control bit), go down some arbitrary edge in  $T'$ . Then alternate adding all children of the present vertices into  $T''$ , and passing down some arbitrary edge. If  $T'$  is perfect, then so is  $T''$ , and moreover,  $T'' \subseteq T$  in that case.

We need also to compute  $a$ . To produce a possible candidate, we attempt to compute the left-most branch  $q$  of  $T'$ . If we ever reach a leaf (which never happens if  $T'$  is perfect), then we continue  $q$  by constant 0. In any case, let  $q'$  be the even digits of  $q$ : if  $T'$  is a perfect subtree of  $T_0$  then  $a = q'$ . On the other hand, if  $(\langle q_0, t_0 p_0 \rangle, \langle q_1, t_1 p_1 \rangle, \dots)$  lists  $[T_0]$  then  $a = q_0$ . Thus  $a = q_0$  or  $a = q'$ . As in the proof of Proposition 7.14 it follows that we can compute  $a$  from  $q_0$ ,  $q'$  and  $\{a\}$ .  $\square$

**Proposition 7.16.**  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \times \text{Det}_\Sigma \equiv_w \text{Det}_\Sigma$ .

*Proof.* By Theorem 6.21, we have  $\text{UC}_{\mathbb{N}^{\mathbb{N}}} \leq_w \text{FindWS}_\Delta$ , i.e. we can compute a  $\Delta_1^0$ -game  $G'_1$  from  $\{a\}$  such that Player 1 wins  $G'_1$ , and from a winning strategy of Player 1 in  $G'_1$  we can compute  $a$ . Let  $G'_2$  be the game with the roles of Player 1 and Player 2 exchanged, which is still  $\Delta_1^0$ . Now we construct a  $\Sigma_1^0$  game  $G''$  from a  $\Sigma_1^0$ -game  $G$ , and from  $G'_1$  and  $G'_2$ .

The players start playing  $G$  and  $G'_2$  in parallel. If Player 2 wins both of these, he wins in  $G''$ . Else, if he loses one of them (which would happen at some finite time), the players proceed to play  $G'_1$ , and whoever wins  $G'_1$  wins  $G''$ . W.l.o.g. we assume that Player 2 can choose to lose  $G$  right at the start of  $G''$ .

Since by assumption Player 2 has a winning strategy in  $G'_2$ , and Player 1 has a winning strategy in  $G'_1$ , the winning strategies of Player 2 are exactly those that consists of playing winning strategies in  $G$  and  $G'_2$  simultaneously. On the other hand, Player 1 can win the game

for sure only by first playing a winning strategy in  $G$  (and arbitrarily in  $G'_2$ ), followed by a winning strategy in  $G'_1$ .

From a Nash equilibrium of the whole game we thus obtain a Nash equilibrium in  $G$  by consider how the players play in  $G$ . Furthermore, we consider how Player 1 plays in the copy of  $G'_1$  played when Player 2 loses in  $G$  right at the start of  $G''$ , and how Player 2 plays in  $G'_2$ , and compute two candidates  $q_0, q_1$  for  $a$  from that. As in the proof of Proposition 7.14, we can then compute  $a$  from  $\{a\}, q_0$  and  $q_1$ .  $\square$

Here the difference between  $w\text{PTT}_2$  and  $\text{PTT}_2$  is revealed, as the former is more sensitive to products. We recall that a Weihrauch degree is called *fractal*, if it has a representative  $f : \subseteq \mathbb{N}^{\mathbb{N}} \rightrightarrows \mathbb{N}^{\mathbb{N}}$  such that for any  $w \in \mathbb{N}^{<\omega}$  such that  $w\mathbb{N}^{\mathbb{N}} \cap \text{dom}(f) \neq \emptyset$  it holds that  $f|_{w\mathbb{N}^{\mathbb{N}}} \equiv_w f$ . Most of the degrees considered in this articles are fractals, including  $w\text{PTT}_2$ .

**Proposition 7.17.** If  $f$  is a fractal and  $\text{LPO} \times f \leq_w w\text{PTT}_2$ , then  $f \leq_w C_{\mathbb{N}^{\mathbb{N}}}$ .

*Proof.* W.l.o.g. assume that  $f : \subseteq \mathbb{N}^{\mathbb{N}} \rightrightarrows \mathbb{N}^{\mathbb{N}}$  witnesses its own fractality.

Fix a reduction of  $\text{LPO} \times f$  to  $w\text{PTT}_2$  and let  $K_1$  be the computable function that transforms the output of  $w\text{PTT}_2$  and the original input of  $\text{LPO} \times f$  into the answer to the  $\text{LPO}$ -instance. We distinguish the following cases:

1. There exists  $0^n, w \in \mathbb{N}^{<\omega}$ , a finite tree  $T$ , and a finite prefix of a list  $\langle 0q_0, 0q_1, 0q_2, \dots \rangle$  such that  $K_1$  provides its answer upon reading those (as input for  $\text{LPO}$ , input for  $f$ , first and second component of the output of  $w\text{PTT}_2$ , in that order).

Then by fixing the input to  $\text{LPO}$  to something consistent with  $0^n$  and incompatible with the answer provided, we can make sure that the reduction needs to avoid the prefix to be valid for any input to  $f$  extending  $w$ . But this can only be achieved by making the input to  $w\text{PTT}_2$  having uncountable body and not having  $T$  as prefix of any perfect subtree. This means in particular that we are dealing with an input to  $\text{PTT}_1$ . As  $f$  is a fractal, restricting to those of its inputs extending  $w$  does not decrease its Weihrauch degree, and we conclude  $f \leq_w C_{\mathbb{N}^{\mathbb{N}}}$ .

2. For no  $0^n, w \in \mathbb{N}^{<\omega}$ , finite tree  $T$ , and finite prefix of a list  $\langle 0q_0, 0q_1, 0q_2, \dots \rangle$ ,  $K_1$  provides its answer upon reading those.

If we fix the  $\text{LPO}$ -input to be  $0^\omega$ , we see that to ensure that  $K_1$  behaves correctly, the list-component of the output of  $w\text{PTT}_2$  must actually list some elements. This can only be guaranteed if the input to  $w\text{PTT}_2$  is a tree with countable non-empty body, i.e. is already in the domain of  $\text{List}$ . We thus conclude  $f \leq_w \text{List} \equiv_w UC_{\mathbb{N}^{\mathbb{N}}}$  (by Theorem 6.5) and, a fortiori,  $f \leq_w C_{\mathbb{N}^{\mathbb{N}}}$ .  $\square$

**Corollary 7.18.**  $\text{LPO} \times w\text{PTT}_2 \not\leq_w w\text{PTT}_2$ .

**Corollary 7.19.**  $w\text{PTT}_2 <_w \text{PTT}_2$ .

*Proof.* By contrasting Corollary 7.18 and Proposition 7.15.  $\square$

We shall see that  $w\text{PTT}_2$  is still closed under some non-trivial products. For that, let  $\text{NON} : 2^{\mathbb{N}} \rightrightarrows 2^{\mathbb{N}}$  be defined via  $q \in \text{NON}(p)$  iff  $q \not\leq_T p$ ; i.e.  $\text{NON}$  is the function corresponding to the theorem asserting the existence of sets non-computable in any given set.

**Proposition 7.20.**  $\text{NON} \times w\text{PTT}_2 \leq_w w\text{PTT}_2$ .

*Proof.* Fix a Turing functional  $\Phi$  such that for every  $p \in 2^{\mathbb{N}}$ ,  $\Phi^p$  is an injective enumeration of  $p'$ , the Turing jump of  $p$ . Let  $\hat{p} \in \mathbb{N}^{\mathbb{N}}$  be such that for every  $n$  we have that  $\hat{p}(n) = 0$  implies  $n \notin p'$  and  $\hat{p}(n) > 0$  implies  $\Phi^p(p(n) - 1) = n$ . Then  $\hat{p}$  is Turing equivalent to  $p'$  and hence  $\hat{p} \not\leq_T p$ .

Notice that the function from  $2^{\mathbb{N}}$  to  $\mathcal{A}(\mathbb{N}^{\mathbb{N}})$  which sends  $p$  to  $\{\hat{p}\}$  is computable. Therefore, from  $(p, A) \in 2^{\mathbb{N}} \times \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  we can compute  $\{\hat{p}\} \times (\{0^\omega\} \cup 1A) \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$ . From any solution to  $wPTT_2(\{\hat{p}\} \times (\{0^\omega\} \cup 1A))$  we can compute a solution to  $wPTT_2(A)$  with the argument of the first part of the proof of Proposition 7.15. Moreover, any solution to  $wPTT_2(\{\hat{p}\} \times (\{0^\omega\} \cup 1A))$  is  $\geq_T \hat{p}$ , and hence solves  $NON(p)$ .  $\square$

In [18], products with LPO and NON are used to separate Weihrauch degrees in a similar fashion.

## 8 $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}$ – a candidate for $ATR_0$ ?

Our separation proofs of principles like  $Det_{\Sigma}$  and  $PTT_2$  from  $C_{\mathbb{N}^{\mathbb{N}}}$  relied on being able to transform an arbitrary closed subset into an input for the former, with specified behaviour occurring only for non-empty closed sets. We can capture this using the notion of *total continuation* of closed choice on  $\mathbb{N}^{\mathbb{N}}$ :

**Definition 8.1.** Let  $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}} : \mathcal{A}(\mathbb{N}^{\mathbb{N}}) \Rightarrow \mathbb{N}^{\mathbb{N}}$  be defined via  $p \in \mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}(A)$  iff  $A \neq \emptyset \Rightarrow p \in A$ .

In the same vein, we can define the total continuation of other choice principles. The computable compactness of  $2^{\mathbb{N}}$  yields  $\mathbf{TC}_{2^{\mathbb{N}}} \equiv_W C_{2^{\mathbb{N}}}$ . The principle  $\mathbf{TC}_N$  was studied in [31].

**Proposition 8.2.** 1.  $C_{\mathbb{N}^{\mathbb{N}}} <_W \mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}$ ;

2.  $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}} <_W LPO \times \mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}$ ;
3. If  $NON \times f \leq_W \mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}$ , then  $f \leq_W C_{\mathbb{N}^{\mathbb{N}}}$ ;
4.  $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}} <_W wPTT_2$ ;
5.  $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}} <_W Det_{\Sigma}$ ;
6.  $[if \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^{\mathbb{N}}} \text{ else } UC_{\mathbb{N}^{\mathbb{N}}}] <_W \mathbf{TC}_{\mathbb{N}^{\mathbb{N}}} \times C_{\mathbb{N}^{\mathbb{N}}}$ .

*Proof.* 1. The reduction is trivial. Separation follows from  $LPO \star C_{\mathbb{N}^{\mathbb{N}}} \equiv_W C_{\mathbb{N}^{\mathbb{N}}}$  and  $\chi_{\Pi_1^1} \leq_W LPO \star \mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}$  (the latter is straightforward because  $LPO$  can check whether the output of  $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}(A)$  belongs to  $A$ ).

2. Again, the reduction is trivial. For the separation, assume that  $LPO \times \mathbf{TC}_{\mathbb{N}^{\mathbb{N}}} \leq_W \mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}$  via computable  $H, K_1, K_2$ . Recall that  $LPO(r) = 1$  iff  $r = 0^\omega$ . Consider the input  $0^\omega$  for  $LPO$  and  $N^{\mathbb{N}} \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  (coded as some name  $t$ ) for  $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}$  on the left. There has to be some  $p \in \mathbb{N}^{\mathbb{N}}$  such that  $K_1(0^\omega, t, p) = 1$ . By continuity, we find that  $K_1(0^k q, t_{\leq k} t', p) = 1$  for sufficiently large  $k$  and arbitrary  $q, t'$ .

For any  $A \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$  we can compute some name of the form  $t_{\leq k} t'$ . Now consider what happens if the inputs on the left are  $0^k 1^\omega$  and some  $t_{\leq k} t'$ : If  $H(0^k 1^\omega, t_{\leq k} t')$  ever returns a name for the empty set, then  $p$  is a valid solution to  $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}}$  on the right. But then  $K_1$  will answer incorrectly 1. Thus,  $H(0^k 1^\omega, t_{\leq k} t')$  never returns a name for the empty set. But then we obtain a reduction  $\mathbf{TC}_{\mathbb{N}^{\mathbb{N}}} \leq_W C_{\mathbb{N}^{\mathbb{N}}}$ , contradicting (1).

3. As  $\text{TC}_{\mathbb{N}^{\mathbb{N}}}(\emptyset)$  has computable solutions, the reduction  $\text{NON} \times f \leq_w \text{TC}_{\mathbb{N}^{\mathbb{N}}}$  already has to be a reduction to  $\text{C}_{\mathbb{N}^{\mathbb{N}}}$ .
4. The reduction given in Proposition 6.4 works for this, by using the following observation: given  $A \in \mathcal{A}(\mathbb{N}^{\mathbb{N}})$ ,  $T \in \mathbf{Tr}$  such that  $[T] = A \times \mathbb{N}^{\mathbb{N}}$  and  $(T', \langle b_0 p_0, b_1 p_1, \dots \rangle) \in \text{PTT}_2(T)$ , if we realize that  $T'$  is not pruned (which can happen only if  $A = \emptyset$ ) we can continue our output with  $0^\omega$ .  
Strictness follows by (3), Proposition 7.20 and Corollary 7.5.
5. The reduction given in Proposition 6.19 works for this, by using the following observation: if  $A = \emptyset$  then Player 1 has a winning strategy in the  $\Sigma_1^0$  game we constructed (in fact, any strategy for 1 is winning), however following the strategy for 2 provided by  $\text{Det}_{\Sigma}$  we find an element of  $\text{TC}_{\mathbb{N}^{\mathbb{N}}}(A)$ .  
Strictness follows by (2), Proposition 7.16 and Corollary 7.5.
6. The arguments used to establish Lemma 6.8 or 6.22 show that the total continuation  $\text{TUC}_{\mathbb{N}^{\mathbb{N}}}$  of  $\text{UC}_{\mathbb{N}^{\mathbb{N}}}$  (i.e. the total multivalued function defined on  $\mathcal{A}(\mathbb{N}^{\mathbb{N}})$  which extends  $\text{UC}_{\mathbb{N}^{\mathbb{N}}}$  and is defined as  $\mathbb{N}^{\mathbb{N}}$  on non-singletons) is reducible to  $\text{C}_{\mathbb{N}^{\mathbb{N}}}$ . For example, given an arbitrary closed  $A \subseteq \mathbb{N}^{\mathbb{N}}$  we can compute the nonempty  $\Sigma_1^1$  set of the mCB-certificates of  $A$  and, choosing an element in it, compute the list of the elements of  $A$  whenever  $A$  is a countable, and in particular a singleton.

Thus, we can consider  $\text{TC}_{\mathbb{N}^{\mathbb{N}}} \times \text{TUC}_{\mathbb{N}^{\mathbb{N}}}$  in place of  $\text{TC}_{\mathbb{N}^{\mathbb{N}}} \times \text{C}_{\mathbb{N}^{\mathbb{N}}}$ . Given some input  $b, A, B$  to  $[\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}]$  we ignore  $b$ , we feed  $A$  to  $\text{TC}_{\mathbb{N}^{\mathbb{N}}}$ , and  $B$  to  $\text{TUC}_{\mathbb{N}^{\mathbb{N}}}$ . Any resulting output pair is a valid output to  $[\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}]$ .

To see that  $\text{TC}_{\mathbb{N}^{\mathbb{N}}} \times \text{C}_{\mathbb{N}^{\mathbb{N}}} \not\equiv_w [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}]$  first notice that  $\text{TC}_{\mathbb{N}^{\mathbb{N}}} \times \text{C}_{\mathbb{N}^{\mathbb{N}}} \times \text{C}_{\mathbb{N}^{\mathbb{N}}} \equiv_w \text{TC}_{\mathbb{N}^{\mathbb{N}}} \times \text{C}_{\mathbb{N}^{\mathbb{N}}}$ . On the other hand, we have

$$[\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}] \times \text{C}_{\mathbb{N}^{\mathbb{N}}} \not\leq_w [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}] :$$

otherwise, since by Corollaries 7.7 and 3.6 we have  $\text{PTT}_2 \leq_w [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}]$  and  $\text{NHA} \leq_w \text{C}_{\mathbb{N}^{\mathbb{N}}}$ , we would have  $\text{PTT}_2 \times \text{NHA} \leq_w [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}]$  and Proposition 7.9 would imply  $\text{PTT}_2 \leq_w \text{C}_{\mathbb{N}^{\mathbb{N}}}$ , against Corollary 7.5.  $\square$

**Corollary 8.3.**  $\text{PTT}_2^* \equiv_w \text{Det}_{\Sigma}^* \equiv_w \text{TC}_{\mathbb{N}^{\mathbb{N}}}^*$ .

*Proof.*  $\text{TC}_{\mathbb{N}^{\mathbb{N}}}^* \leq_w \text{PTT}_2^*$  is immediate from Proposition 8.2(4). On the other hand we have

$$\text{PTT}_2^* \leq_w [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } \text{C}_{\mathbb{N}^{\mathbb{N}}} \text{ else } \text{UC}_{\mathbb{N}^{\mathbb{N}}}]^* \leq_w (\text{TC}_{\mathbb{N}^{\mathbb{N}}} \times \text{C}_{\mathbb{N}^{\mathbb{N}}})^* \leq_w \text{TC}_{\mathbb{N}^{\mathbb{N}}}^*,$$

using Corollary 7.7 and Proposition 8.2(6).

The argument for  $\text{Det}_{\Sigma}^*$  is similar.  $\square$

It is reasonable to expect a Weihrauch degree corresponding to an axiom system from reverse mathematics to be closed under finite parallelization. For candidates for  $\text{WKL}_0$  or  $\text{ACA}_0$  this happens inherently. Here, we might need to demand it explicitly, and thus consider the degree  $\text{TC}_{\mathbb{N}^{\mathbb{N}}}^*$  rather than any directly defined one to be one of the most promising candidates.

A potentially convenient way to think about the separation between  $\text{C}_{\mathbb{N}^{\mathbb{N}}}$  and  $\text{TC}_{\mathbb{N}^{\mathbb{N}}}$  is in terms of translations between truth values.  $\text{TC}_{\mathbb{N}^{\mathbb{N}}}$  allows us to treat a single  $\Pi_1^1$ -set as an open set, whereas  $\text{C}_{\mathbb{N}^{\mathbb{N}}}$  cannot even bridge the gap from  $\Sigma_1^1$  to Borel.

**Proposition 8.4.**  $(\text{id} : \mathbb{S}_{\Pi_1^1} \rightarrow \mathbb{S}) \leq_W \text{TC}_{\mathbb{N}^\mathbb{N}}$ , but  $(\text{id} : \mathbb{S}_{\Sigma_1^1} \rightarrow \mathbb{S}_B) \not\leq_W C_{\mathbb{N}^\mathbb{N}}$ .

*Proof.* For the reduction, we observe that  $A = \emptyset$  iff  $p \notin A$  for some  $p \in \text{TC}_{\mathbb{N}^\mathbb{N}}(A)$ .

For the non-reduction, we recall that  $\text{id} : \mathbb{S}_B \rightarrow \mathbf{2} \leq_W \text{UC}_{\mathbb{N}^\mathbb{N}}$  was shown in [37], and that  $\text{UC}_{\mathbb{N}^\mathbb{N}} * C_{\mathbb{N}^\mathbb{N}} \equiv_W C_{\mathbb{N}^\mathbb{N}}$  as shown in [5]. Thus, assuming the reduction would hold, we would even have that  $(\text{id} : \mathbb{S}_{\Pi_1^1} \rightarrow \mathbf{2}) \leq_W C_{\mathbb{N}^\mathbb{N}}$ , which contradicts [5, Theorem 7.7] because the unique realizer of  $\text{id} : \mathbb{S}_{\Pi_1^1} \rightarrow \mathbf{2}$  is not effectively Borel measurable.  $\square$

Next, we shall see that the additional computational power of  $\text{TC}_{\mathbb{N}^\mathbb{N}}$  (even of its parallelization  $\widehat{\text{TC}_{\mathbb{N}^\mathbb{N}}}$ ) over  $\text{UC}_{\mathbb{N}^\mathbb{N}}$  concerns only multivalued problems.

**Theorem 8.5.** The following are equivalent for single-valued  $f : \mathbf{X} \rightarrow \mathbb{N}^\mathbb{N}$ :

1.  $f \leq_W \text{UC}_{\mathbb{N}^\mathbb{N}}$ ;
2.  $f \leq_W \widehat{\text{TC}_{\mathbb{N}^\mathbb{N}}}$ .

*Proof.* That 1 implies 2 is trivial. For the other direction, we show that for single-valued  $f : \subseteq \mathbb{N}^\mathbb{N} \rightarrow \{0, 1\}$ ,  $f \leq_{sW} \widehat{\text{TC}_{\mathbb{N}^\mathbb{N}}}$  implies  $f \leq_W \Delta_1^1\text{-CA}$  and invoke Theorem 3.11. This suffices. In fact we can consider codomain  $\{0, 1\}$  instead of  $\mathbb{N}^\mathbb{N}$  because  $\mathbb{N}^\mathbb{N}$  computably embeds into  $2^\mathbb{N}$  and because  $\text{UC}_{\mathbb{N}^\mathbb{N}}$  is parallelizable. We can start from a strong Weihrauch reduction because  $\widehat{\text{TC}_{\mathbb{N}^\mathbb{N}}}$  is a cylinder.

Assume that  $f : \subseteq \mathbb{N}^\mathbb{N} \rightarrow \{0, 1\}$  and  $f \leq_{sW} \widehat{\text{TC}_{\mathbb{N}^\mathbb{N}}}$  via computable  $K, H$ . The outer reduction witness  $K$  essentially consists of two open sets  $U^0, U^1 \in \mathcal{O}((\mathbb{N}^\mathbb{N})^\mathbb{N})$ , while the inner reduction witness  $H$  gives us for each  $p \in \mathbb{N}^\mathbb{N}$  a sequence  $(A_n(p))_{n \in \mathbb{N}}$  of closed sets. For  $S \subseteq \mathbb{N}$  and  $U \in \mathcal{O}((\mathbb{N}^\mathbb{N})^\mathbb{N})$ , let  $\pi_S(U)$  denote the projection of  $U$  to the components in  $S$ . Now we find that:

$$f(p) = b \Leftrightarrow \forall S \subseteq \mathbb{N} \prod_{n \in S} A_n(p) \subseteq \pi_S(U^b).$$

(Notice that  $\prod_{n \in \mathbb{N}} A_n(p) \subseteq U^b$  does not imply  $f(p) = b$  in general because some of the  $A_n(p)$  could be empty.) This is a  $\Pi_1^1$ -condition. Since exactly one of  $f(p) = 0$  and  $f(p) = 1$  holds, we thus have a valid instance for  $\Delta_1^1\text{-CA}$ .  $\square$

In particular,  $\widehat{\text{TC}_{\mathbb{N}^\mathbb{N}}}$  does not reach the level of  $\Pi_1^1\text{-CA}_0$ .

**Corollary 8.6.**  $\chi_{\Pi_1^1} \not\leq_W \widehat{\text{TC}_{\mathbb{N}^\mathbb{N}}}$ .

## 9 Open questions and discussion

The results reported in Section 7 immediately lead to three interlinked questions, which unfortunately we have been unable to resolve so far:

**Question 9.1.** Does  $\text{Det}_\Sigma \equiv_W [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } \text{UC}_{\mathbb{N}^\mathbb{N}}]$ ?

**Question 9.2.** Does  $\text{PTT}_2 \equiv_W [\text{if } \mathbb{S}_{\Sigma_1^1} \text{ then } C_{\mathbb{N}^\mathbb{N}} \text{ else } \text{UC}_{\mathbb{N}^\mathbb{N}}]$ ?

**Question 9.3.** How do  $\text{PTT}_2$  and  $\text{Det}_\Sigma$  relate?

We would expect that other theorems equivalent to ATR<sub>0</sub> (e.g. open Ramsey) exhibit similar behaviour, i.e. a non-constructive disjunction between cases equivalent to C<sub>ℕ</sub> and UC<sub>ℕ</sub> respectively. Proving any reductions between the two-sided versions of these theorems could be very illuminating. Until then, we might have to settle for classifications in the Weihrauch lattice up to \*, and strive to understand better the degree TC<sub>ℕ</sub><sup>\*</sup>.

Brattka has also raised the question whether the strong two-sided versions, which return an answer on the applicable case together with a witness, are worthwhile studying. It seems conceivable that finding reductions here would be easier. Up to \*, these problems would have the degree TC<sub>ℕ</sub><sup>\*</sup> × χ<sub>Π<sup>1</sup></sub><sup>\*</sup>. Would this be an acceptable candidate for an ATR<sub>0</sub>-equivalent, or is this degree too close to Π<sup>1</sup>-CA<sub>0</sub>?

Given that TC<sub>ℕ</sub><sup>\*</sup> is not closed under composition, one could make the case that TC<sub>ℕ</sub><sup>◊</sup> (its closure under generalized register machines, cf. [31]) is the better candidate. Note that TC<sub>ℕ</sub><sup>◊</sup> ≡<sub>W</sub> (TC<sub>ℕ</sub><sup>\*</sup> × χ<sub>Π<sup>1</sup></sub>)<sup>◊</sup>, so the distinction between the weak and strong two-sided versions of the theorems would disappear here. How well justified this step would be in particular depends on whether there exists a natural theorem equivalent to ATR<sub>0</sub> in reverse mathematics where ATR<sub>0</sub> is actually used in a sequential way, i.e. a theorem naturally associated with a Weihrauch degree not reducible to TC<sub>ℕ</sub><sup>\*</sup>.

## Acknowledgements

In the earlier stages of this research Marcone collaborated with Andrea Cettolo, and some of the proofs were obtained jointly with him. Pauly began working on this project while being a visiting fellow at the Isaac Newton Institute for Mathematical Sciences in the programme ‘Mathematical, Foundational and Computational Aspects of the Higher Infinite’. He thanks Vasco Brattka, Jun Le Goh, Luca San Mauro and Richard Shore for inspiring conversations. The research project benefitted from discussion at the Dagstuhl seminars 15392 ‘Measuring the Complexity of Computational Content: Weihrauch Reducibility and Reverse Analysis’ and 18361 ‘Measuring the Complexity of Computational Content: From Combinatorial Problems to Analysis’.

Kihara’s research was partially supported by JSPS KAKENHI Grant 17H06738, 15H03634, and the JSPS Core-to-Core Program (A. Advanced Research Networks). Marcone’s research was partially supported by PRIN 2012 Grant “Logica, Modelli e Insiemi” and by the departmental PRID funding “HiWei — The higher levels of the Weihrauch hierarchy”.
